## Foreword

ISO (the International Organization for Standardization) is a worldwide federation of national standards bodies (ISO member bodies). The work of preparing International Standards is normally carried out through ISO technical committees. Each member body interested in a subject for which a technical committee has been established has the right to be represented on that committee. International organizations, governmental and non-governmental, in liaison with ISO, also take part in the work. ISO collaborates closely with the International Electrotechnical Commission (IEC) on all matters of electrotechnical standardization.

International Standards are drafted in accordance with the rules given in the ISO/IEC Directives, Part 2.

The main task of technical committees is to prepare International Standards. Draft International Standards adopted by the technical committees are circulated to the member bodies for voting. Publication as an International Standard requires approval by at least 75 % of the member bodies casting a vote.

ISO 13232-4 was prepared by Technical Committee ISO/TC 22, *Road vehicles*, Subcommittee SC 22, *Motorcycles*.

This second edition cancels and replaces the first version (ISO 13232-4:1996), which has been technically revised.

ISO 13232 consists of the following parts, under the general title *Motorcycles — Test and analysis procedures for research evaluation of rider crash protective devices fitted to motorcycles*:

- *Part 1: Definitions, symbols and general considerations*
- *Part 2: Definition of impact conditions in relation to accident data*
- *Part 3: Motorcyclist anthropometric impact dummy*
- *Part 4: Variables to be measured, instrumentation and measurement procedures*
- *Part 5: Injury indices and risk/benefit analysis*
- *Part 6: Full-scale impact-test procedures*
- *Part 7: Standardized procedures for performing computer simulations of motorcycle impact tests*
- *Part 8: Documentation and reports*

## Introduction

ISO 13232 has been prepared on the basis of existing technology. Its purpose is to define common research methods and a means for making an overall evaluation of the effect that devices which are fitted to motorcycles and intended for the crash protection of riders, have on injuries, when assessed over a range of impact conditions which are based on accident data.

It is intended that all of the methods and recommendations contained in ISO 13232 should be used in all basic feasibility research. However, researchers should also consider variations in the specified conditions (for example, rider size) when evaluating the overall feasibility of any protective device. In addition, researchers may wish to vary or extend elements of the methodology in order to research issues which are of particular interest to them. In all such cases which go beyond the basic research, if reference is to be made to ISO 13232, a clear explanation of how the used procedures differ from the basic methodology should be provided.

ISO 13232 was prepared by ISO/TC 22/SC 22 at the request of the United Nations Economic Commission for Europe Group for Road Vehicle General Safety (UN/ECE/TRANS/SCI/WP29/GRSG), based on original working documents submitted by the International Motorcycle Manufacturers Association (IMMA), and comprising eight interrelated parts.

This revision of ISO 13232 incorporates extensive technical amendments throughout all the parts, resulting from extensive experience with the standard and the development of improved research methods.

In order to apply ISO 13232 properly, it is strongly recommended that all eight parts be used together, particularly if the results are to be published.

# Motorcycles — Test and analysis procedures for research evaluation of rider crash protective devices fitted to motorcycles —

## Part 4:

## Variables to be measured, instrumentation and measurement procedures

### 1 Scope

This part of ISO 13232 specifies requirements for the:

- repeatability and reproducibility of the dynamic measurement procedures for the motorcycle, the opposing vehicle, and the dummy; and
- dummy instrumentation.

ISO 13232 specifies the minimum requirements for research into the feasibility of protective devices fitted to motorcycles, which are intended to protect the rider in the event of a collision.

ISO 13232 is applicable to impact tests involving:

- two-wheeled motorcycles;
- the specified type of opposing vehicle;
- either a stationary and a moving vehicle or two moving vehicles;
- for any moving vehicle, a steady speed and straight-line motion immediately prior to impact;
- one helmeted dummy in a normal seating position on an upright motorcycle;
- the measurement of the potential for specified types of injury by body region;
- evaluation of the results of paired impact tests (i.e. comparisons between motorcycles fitted and not fitted with the proposed devices).

ISO 13232 does not apply to testing for regulatory or legislative purposes.

### 2 Normative references

The following referenced documents are indispensable for the application of this document. For dated references, only the edition cited applies. For undated references, the latest edition of the referenced document (including any amendments) applies.

### 3 Definitions, symbols, and abbreviations

The following terms are defined in ISO 13232-1. For the purposes of this part of ISO 13232, those definitions apply. Additional definitions which could apply to this part of ISO 13232 are also listed in ISO 13232-1:

- aim point;
- blur;
- cursor;
- detachable external cables;
- digitizing surface;
- film analysis frame;
- frame width;
- helmet centroid point;
- high speed photography;
- leading edge;
- magnification;
- motion analyser grid;
- oblique camera;
- off axis;
- output signal voltage;
- overall accuracy of the film analysis;

- primary axis;
- signal gain;
- trailing edge;
- visual resolution.

## 4 Requirements

### 4.1 Electronically recorded variables

#### 4.1.1 Required

The variables listed below shall be recorded in all full-scale impact tests from at least 0,100 s before first MC/OV contact until at least 3,000 s after first MC/OV contact, using the sensors described in 4.4.1:

- a) first MC/OV contact occurrence;
- b) head (nine linear accelerations):
  - 1) bottom centre acceleration in three axes ( $a_1, a_4, a_7$ ),
  - 2) top centre acceleration in two axes ( $a_3, a_6$ ),
  - 3) bottom left acceleration in two axes ( $a_5, a_9$ ),
  - 4) bottom right acceleration in two axes ( $a_2, a_8$ ),
- c) chest:
  - 1) sternum upper left displacement ( $l_{uL}$ ),
  - 2) sternum upper right displacement ( $l_{uR}$ ),
  - 3) sternum lower left displacement ( $l_{lL}$ ),
  - 4) sternum lower right displacement ( $l_{lR}$ ).
- d) upper neck
  - 1) upper neck antero - posterior shear force ( $F_{x,n}$ ),
  - 2) upper neck lateral shear force ( $F_{y,n}$ ),
  - 3) upper neck tension/compression forces ( $F_{z,n}$ ),
  - 4) upper neck lateral bending moment ( $M_{x,n}$ ),
  - 5) upper neck flexion/extension moment ( $M_{y,n}$ ),
  - 6) upper neck torsional moment ( $M_{z,n}$ ).

**4.1.1.1 Additionally required for leg protective device evaluation**

- a) left and right upper femur:
  - 1) axial force ( $F_{z,uF}$ ),
  - 2) lateral bending moment ( $M_{x,uF}$ ),
  - 3) antero-posterior bending moment ( $M_{y,uF}$ );
- b) left and right upper tibia:
  - 1) lateral bending moment ( $M_{x,uT}$ ),
  - 2) antero-posterior bending moment ( $M_{y,uT}$ ).

**4.1.2 Not recommended**

The variables listed below should not be recorded because of motorcyclist anthropometric impact dummy biofidelity limitations:

- chest accelerations;
- pelvic accelerations.

**4.1.3 Permissible**

In addition to the required variables listed in 4.1.1, the variables listed below may be recorded:

- a) lumbar spine:
  - 1) antero-posterior shear force ( $F_{x,l}$ ),
  - 2) lateral shear force ( $F_{y,l}$ ),
  - 3) axial force ( $F_{z,l}$ ),
  - 4) lateral bending moment ( $M_{x,l}$ ),
  - 5) antero-posterior bending moment ( $M_{y,l}$ ),
  - 6) torsional moment ( $M_{z,l}$ );
- b) left and right upper femur:
  - 1) axial force ( $F_{z,uF}$ ),
  - 2) lateral bending moment ( $M_{x,uF}$ ),
  - 3) antero-posterior bending moment ( $M_{y,uF}$ ),
  - 4) torsional moment ( $M_{z,uF}$ );
- c) left and right lower femur:

- 1) axial force ( $F_{z,lF}$ ),
  - 2) lateral bending moment ( $M_{x,lF}$ ),
  - 3) antero-posterior bending moment ( $M_{y,lF}$ ),
  - 4) torsional moment ( $M_{z,lF}$ );
- d) left and right upper tibia:
- 1) lateral bending moment ( $M_{x,uT}$ ),
  - 2) antero-posterior bending moment ( $M_{y,uT}$ ),
  - 3) torsional moment ( $M_{z,uT}$ );
- e) left and right lower tibia:
- 1) axial force ( $F_{z,lT}$ ),
  - 2) lateral bending moment ( $M_{x,lT}$ ),
  - 3) antero-posterior bending moment ( $M_{y,lT}$ ).
- f) left and right femur and tibia: frangible bone continuity sensor

#### 4.2 Mechanically recorded variables

The variables listed below shall be recorded in all full-scale impact tests using the sensors described in 4.4.2 and the procedures described in 5.2.3:

- abdomen maximum residual penetration ( $p_{A,max}$ );
- left and right femur fracture occurrence;
- left and right knee varus valgus dislocation occurrence;
- left and right knee torsional dislocation occurrence;
- left and right tibia fracture occurrence.

#### 4.3 Photographic targets to be digitized

The targets listed below shall be digitized at first MC/OV contact, unless otherwise stated.

The high speed photographic data shall be analysed using a motion analyser for which the ratio of the overall accuracy to the magnification is 0,007 or less<sup>1)</sup>.

---

1) A list describing one or more example products which meet these requirements is maintained by the ISO Central Secretariat and the Secretariat of ISO/TC 22/SC 22. The list is maintained for the convenience of users of ISO 13232 and does not constitute an endorsement by ISO of the products listed. Alternative products may be used if they can be shown to lead to the same results.

**4.3.1 Helmet centroid point**

The following helmet centroid point variables shall be determined for the time frame and using the procedures defined in 5.2.4 and Annex A:

- inertial longitudinal position ( $x_h$ );
- inertial lateral position ( $y_h$ );
- inertial vertical position ( $z_h$ ).

**4.3.2 Motorcycle**

Motorcycle targets which shall be digitized include the following:

- upper and lower targets on the top to bottom centre line, visible from the rear view, or front view if only the front camera is used;
- front and rear targets on the front to rear centre line, visible from the MC top view;
- main frame front and rear reference, visible from the MC side view, from at least 10 film analysis frames before first MC/OV contact until at least first MC/OV contact.

**4.3.3 Opposing vehicle**

The opposing vehicle targets which shall be digitized and their locations are given in Table 1.

**Table 1 — Opposing vehicle targets**

Target	Locations
Bonnet centre line	100 mm rearward from the bonnet leading edge 100 mm forward from the bonnet trailing edge
Roof centre line	100 mm rearward from the roof leading edge 100 mm forward from the roof trailing edge
Boot lid centre line	100 mm forward from the boot lid trailing edge 100 mm rearward from the boot lid leading edge
Body side reference <sup>a</sup>	Visible from OV side view camera
<sup>a</sup> From at least 10 film analysis frames before first MC/OV contact until at least first MC/OV contact.	

**4.3.4 Ground**

At least two targets shall be fixed on the ground and shall be visible in each camera prior to and at first MC/OV contact. They shall be at least 2 m apart. The z locations of all target centres shall be equal. At least one of the ground fixed targets shall be visible and undisturbed in each camera from at least 10 film analysis frames before first MC/OV contact until at least first MC/OV contact. Multiple targets should be used to increase the likelihood that at least one is visible and undisturbed during the entire film analysis sequence.

#### 4.3.4.1 MC side view and MC top view

The ground fixed targets which are visible in the MC side view and MC top view cameras shall be aligned such that a line connecting the targets is parallel to the pre-impact centre line or path of the MC.

#### 4.3.4.2 MC rear or MC front view

The ground fixed targets which are visible in the MC rear view or MC front view camera shall be aligned such that a line connecting the targets is perpendicular to the pre-impact centre line of the MC. A third ground fixed target shall be visible and be aligned such that it is at least 1 m above and along the z inertial axis of either of the other two ground fixed targets.

#### 4.3.4.3 OV side view

The ground fixed targets which are visible in the OV side view camera shall be aligned such that a line connecting them is parallel to the pre-impact centre line or path of the OV.

#### 4.3.5 Dummy

The dummy joint target locations, as defined in 5.3.6 of ISO 13232-6, shall be digitized in the film frame immediately preceding first MC/OV contact, according to 5.3.5 of this part of ISO 13232.

If the test data are to be used for simulation comparison, according to 4.5.4 of ISO 13232-7, then these target locations shall also be digitized according to the procedures defined in 5.2.4 of this part of ISO 13232.

### 4.4 Sensor specifications

#### 4.4.1 Electrical

##### 4.4.1.1 Head accelerometers

The head linear accelerations listed in 4.1.1 shall be measured using Endevco accelerometers, model 7264-2000<sup>2)</sup>, mounted using an accelerometer block<sup>3)</sup> as shown in Figure 1a and 1b. The mounting block shall be attached to the Hybrid III head using a mounting base<sup>3)</sup> as shown in Figure 2.

##### 4.4.1.2 Upper neck load cell

The neck variables listed in 4.1.1 shall be measured using a Denton load cell, model 1716<sup>4)</sup>.

---

2) Accelerometer model 7264-2000 is a product supplied by Endevco Corp, San Juan Capistrano, California, USA. This information is given for the convenience of users of ISO 13232 and does not constitute an endorsement by ISO of the product named. Alternative products may be used if they can be shown to lead to the same results.

3) A list describing one or more example products which meet these requirements is maintained by the ISO Central Secretariat and the Secretariat of ISO/TC 22/SC 22. The list is maintained for the convenience of users of ISO 13232 and does not constitute an endorsement by ISO of the products listed. Alternative products may be used if they can be shown to lead to the same results.

4) Load cell model 1716 is a product supplied by Robert A. Denton, Inc., Rochester Hills, Michigan, USA. This information is given for the convenience of users of ISO 13232 and does not constitute an endorsement by ISO of the product named. Alternative products may be used if they can be shown to lead to the same results.

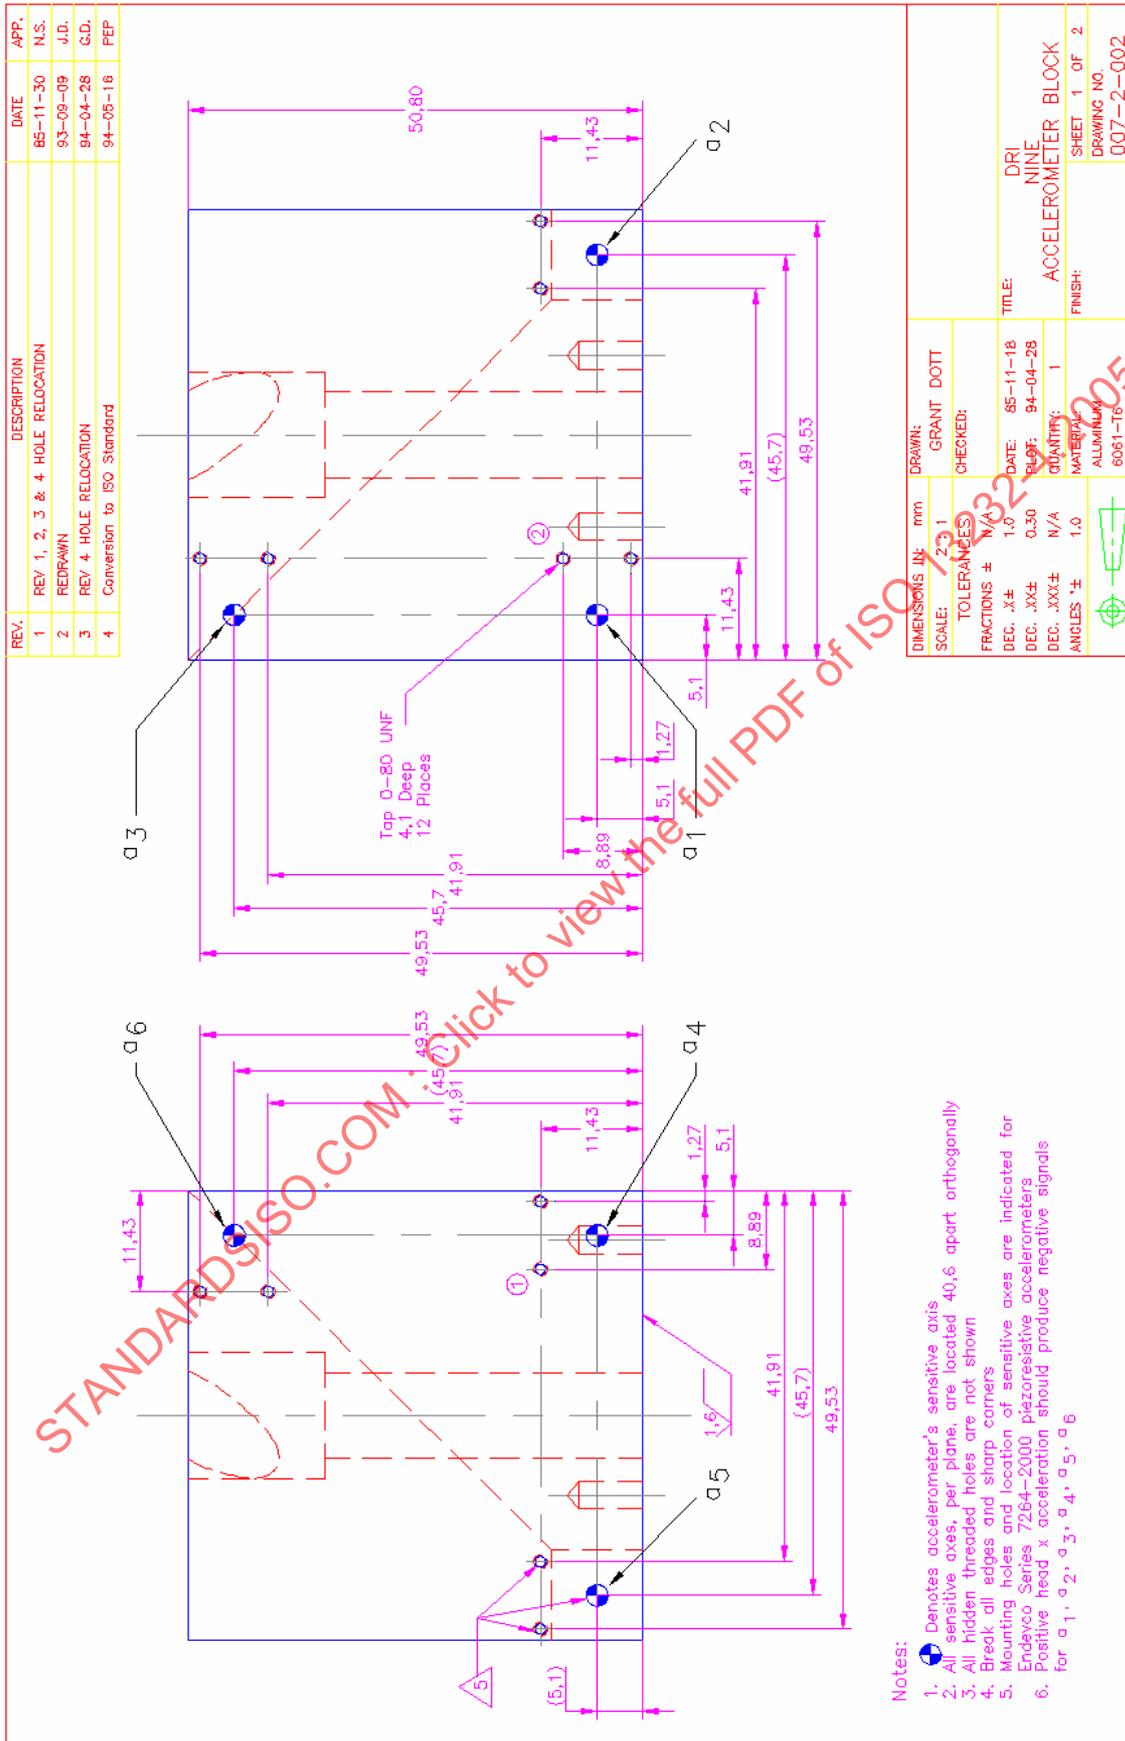

Figure 1a — Nine accelerometer block with accelerometer mounting locations and orientations

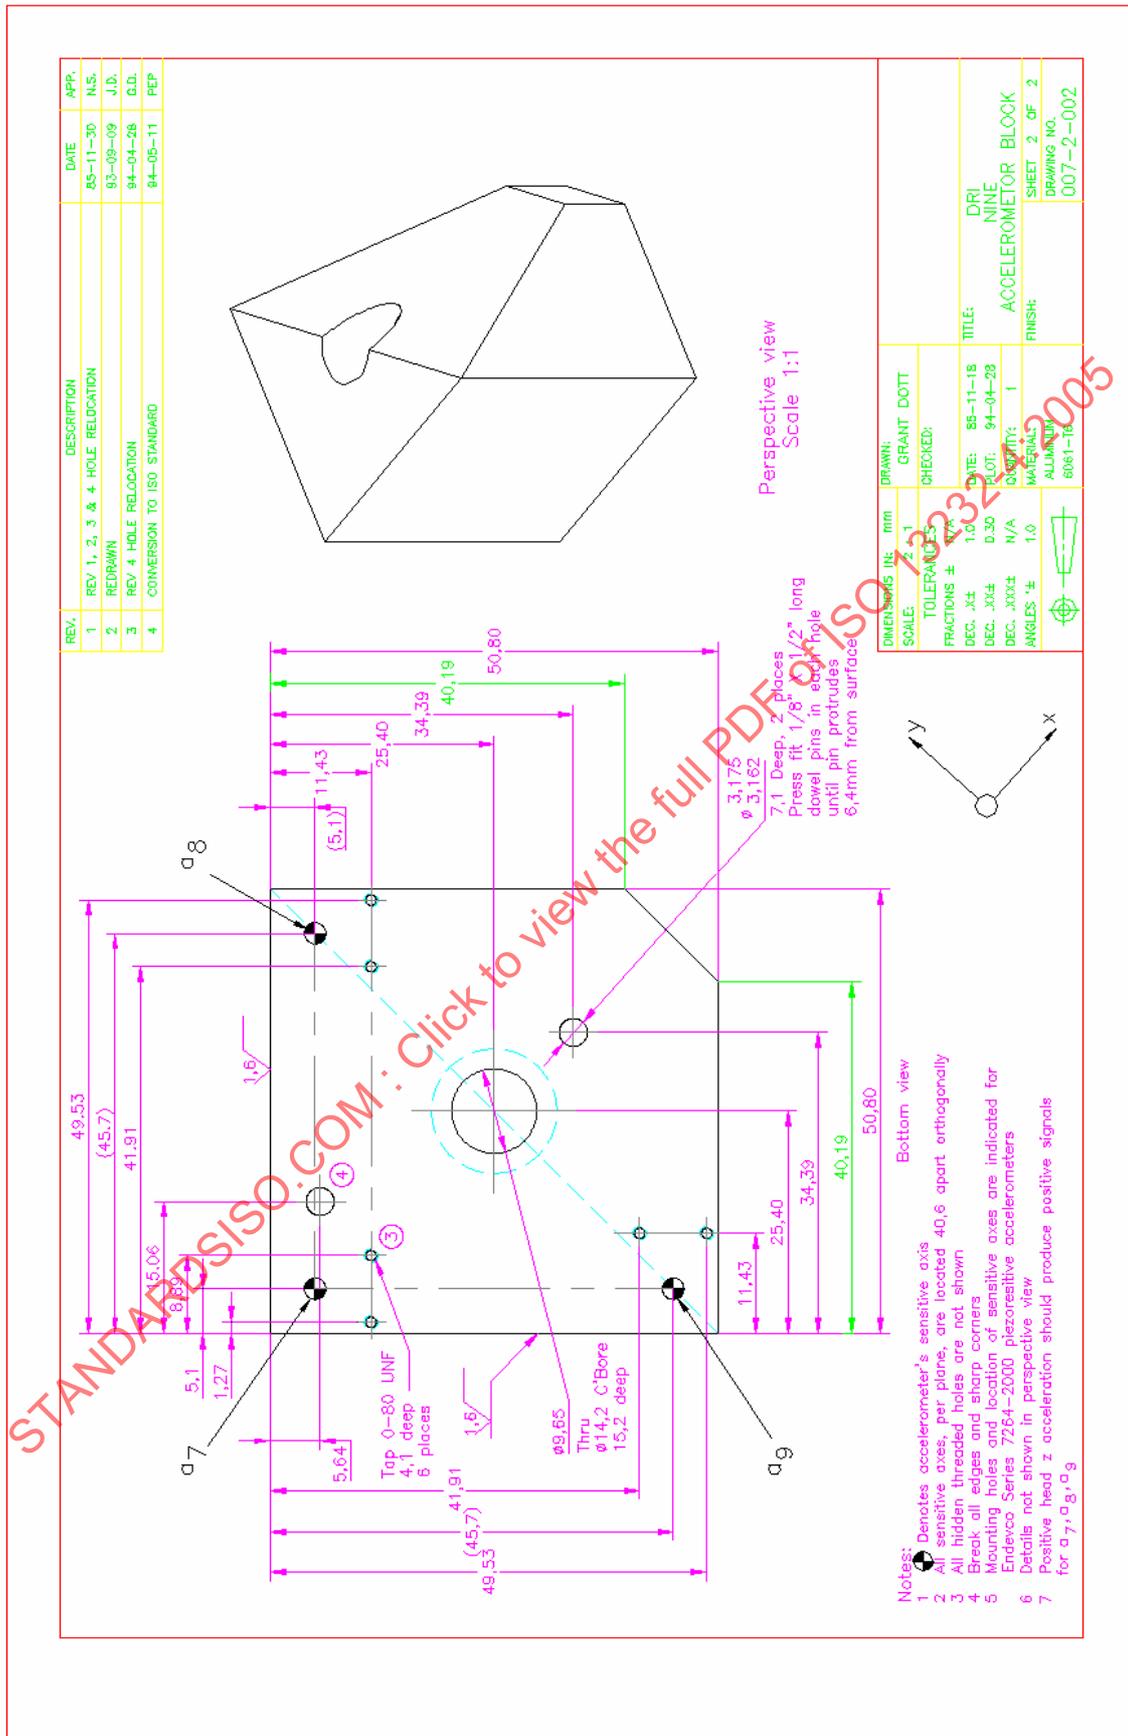

Figure 1b — Nine accelerometer block with accelerometer mounting locations and orientations

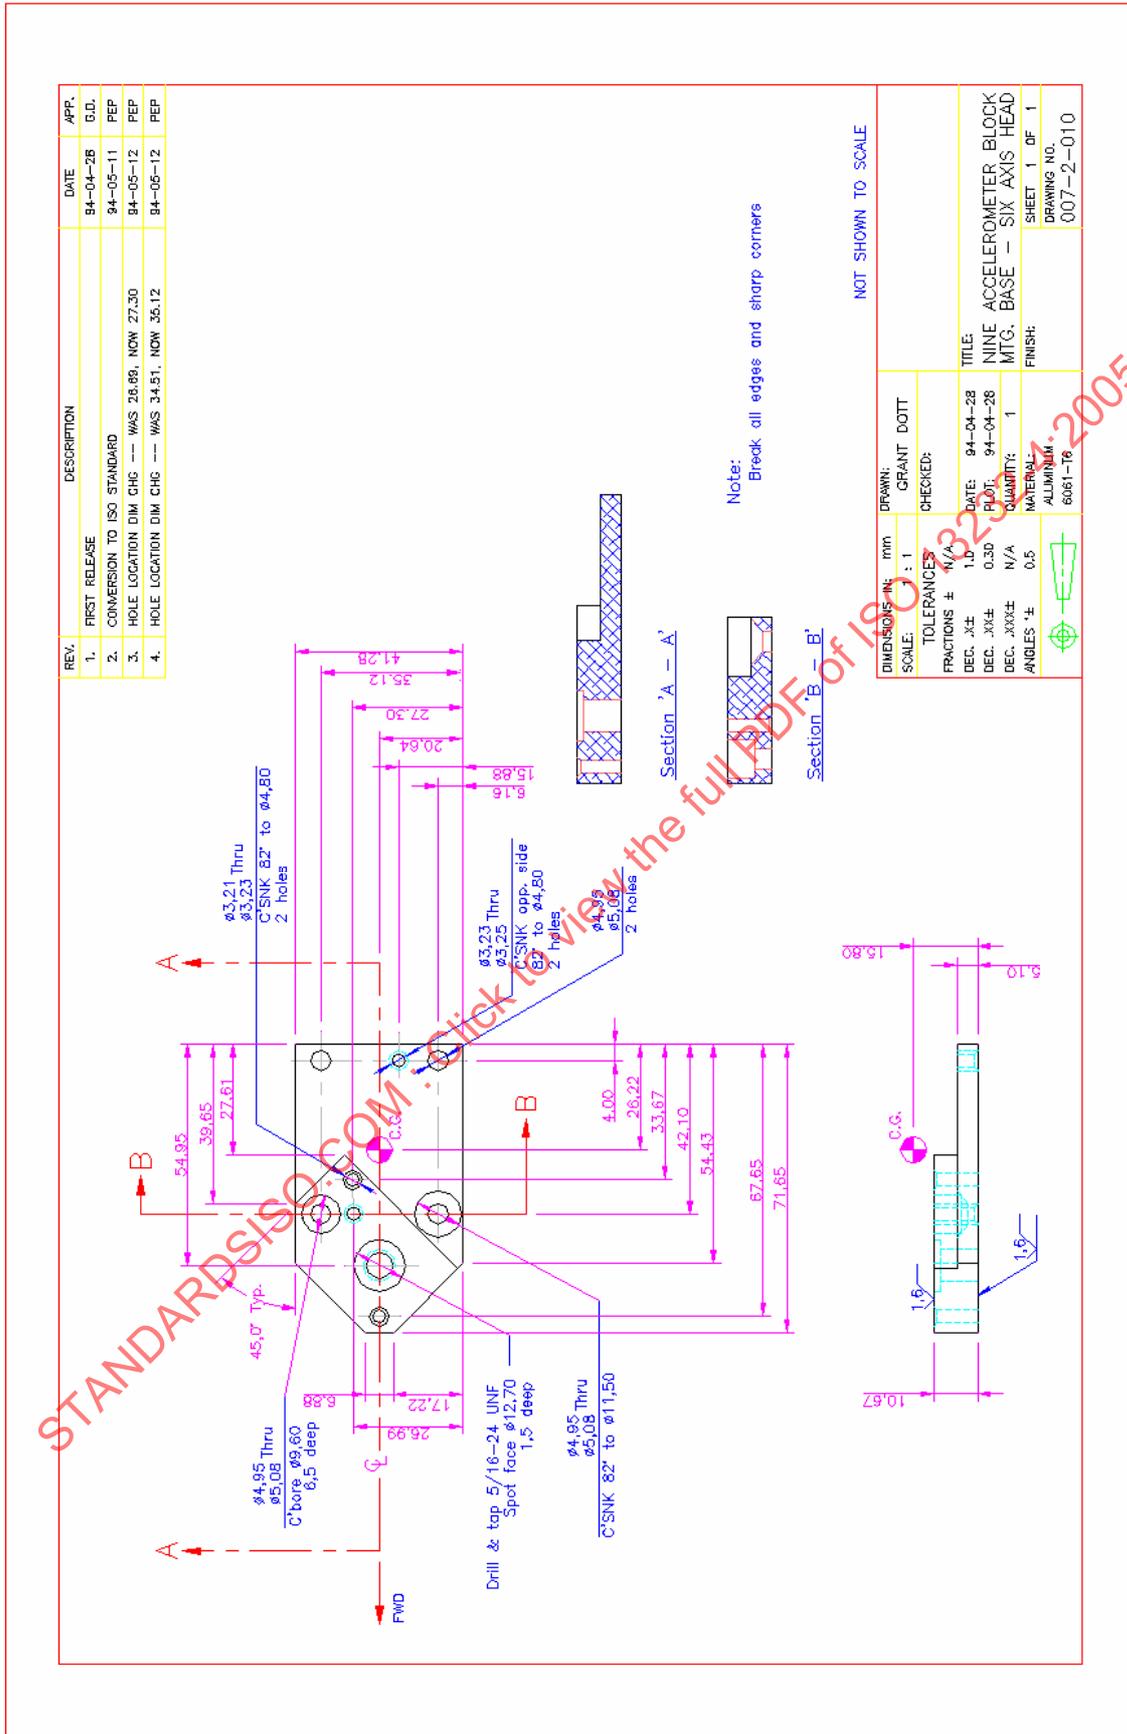

Figure 2 — Nine accelerometer block mounting base

#### 4.4.1.3 Chest potentiometers

The chest displacements listed in 4.1.1 shall be measured using Space Age Control string potentiometers, models 160-321VL and 160-321VR<sup>5)</sup>, mounted as shown in Figure 3<sup>6)</sup>.

Alternative mounting configurations for the chest potentiometers may be used as long as the cable positions shown in Figure 3 are maintained. For example the lower right hand spooling potentiometer shown in Figure 3 could be replaced by a left hand spooling unit mounted below the cable location.

#### 4.4.1.4 Lumbar load cell

The lumbar spine forces and moments listed in 4.1.3 shall be measured using a Denton load cell, model 1708<sup>7)</sup> for six axes or model 1891<sup>7)</sup> for three axes.

#### 4.4.1.5 Upper femur load cells

The upper femur forces and moments listed in 4.1.1.2 and 4.1.3 shall be measured using Denton load cells, model 2693<sup>7)</sup>.

#### 4.4.1.6 Frangible leg bone strain gauges

The strain gauges used to measure the lower femur and upper and lower tibia forces and moments listed in 4.1.1.2 and 4.1.3 shall conform to the specifications listed in Table 2. They shall be mounted on the bones at the locations shown in Figure 4.

**Table 2 — Frangible leg bone strain gauge specifications**

Parameter	Specification
Configuration	Half or full bridge
Resistance	350 ohms
Excitation	2,05 V - 0,05 V to 2,50 V + 0,05 V
Maximum cross axis sensitivity	5%
Gauge factor	2

Each frangible bone strain gauged variable recorded in each full-scale test shall be calibrated according to 5.2.2.

NOTE Frangible bone strain gauges which have been properly mounted and calibrated can provide useful additional information in crash tests regarding the general magnitude, direction and timing of bone forces, prior to or in the absence of bone fracture. However, because they are exposed to damage from various sources, and because of possible installation variations, they might not be reliable in all cases, in particular for the time period during and after a bone fractures. In addition,

- 5) String potentiometer models 160-321VL and 160-321VR are products supplied by Space Age Controls, Inc., Palmdale, California, USA. This information is given for the convenience of users of ISO 13232 and does not constitute an endorsement by ISO of the product named. Alternative products may be used if they can be shown to lead to the same results.
- 6) A list describing one or more example products which meet these requirements is maintained by the ISO Central Secretariat and the Secretariat of ISO/TC 22/SC 22. The list is maintained for the convenience of users of ISO 13232 and does not constitute an endorsement by ISO of the products listed. Alternative products may be used if they can be shown to lead to the same results.
- 7) Load cell models 1708, 1891, and 2693 are products supplied by Robert A. Denton, Inc., Rochester Hills, Michigan, USA. This information is given for the convenience of users of ISO 13232 and does not constitute an endorsement by ISO of the product named. Alternative products may be used if they can be shown to lead to the same results.

like load cells, they sense force in only one location, whereas the force components elsewhere in the bone can be much larger. For these and other reasons, they are not considered appropriate for injury evaluation or frangible bone conformity of production tests.

9/94	-dim	chg	ISO_022	
3/95	-dim	chg	Scale: 1:2	

Figure 4 — Frangible bone strain gauge locations

#### 4.4.1.7 Frangible bone continuity sensor

The frangible bone continuity sensor used to monitor frangible bone breakage shall be mounted on all four bones as shown in Figure 5, using the procedure described in 5.4.

#### 4.4.2 Mechanical

All mechanical sensors shall conform to the specifications given in ISO 13232-3. The sensors shall include:

- an abdominal foam insert;
- frangible femur and tibia bones;
- knee compliance elements;
- knee shear pins.

#### 4.5 Internal data acquisition and recording system specifications<sup>8)</sup>

There should be no external cables attached to the dummy, except during the pre-crash phase, detachable cables to supply power to the internal data acquisition system and the MC/OV contact sensor. A maximum force of 5 N shall be required to detach the cables.

##### 4.5.1 Not recommended external cables

Non-detachable external cables should not be used, but if used, each cable shall have a mass not greater than 1/3 kg and a length not shorter than 12 m. The total mass of all of the cables, between the dummy and the point of attachment to the MC, shall not exceed 4 kg. The cables shall be arranged so that each is unrestrained. They shall not be attached to the MC, the dummy, or any other cable, except at the cable extremities. The cables shall be attached to the dummy by means of a connector attached to the rear portion of the pelvis.

##### 4.5.2 Data acquisition

The data acquisition system shall be capable of recording a minimum of 32 channels, at a minimum bandwidth of 2.5 kHz for analog recording or a minimum sampling rate of 10 kHz for digital recording. The following system specifications shall apply.

###### 4.5.2.1 Sensor excitation

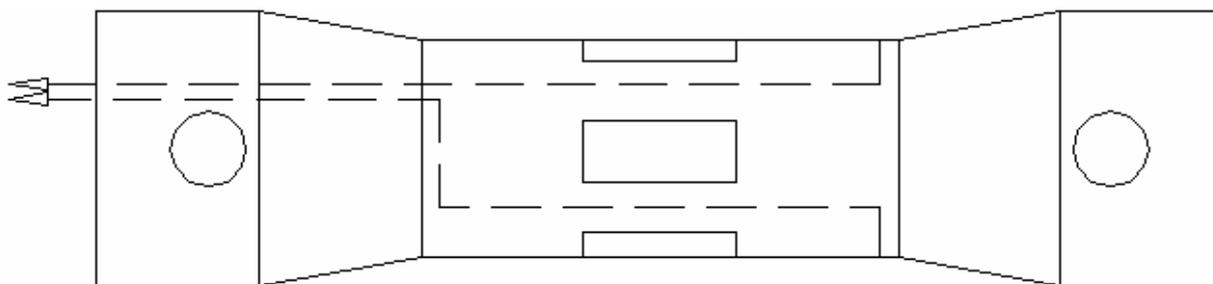

The load cells and accelerometers shall have a  $10,0 \text{ V} \pm 0,2 \text{ V}$  excitation. The potentiometers and strain gauges shall have an excitation of  $2,00 \text{ V} - 0,05 \text{ V}$  to  $2,50 \text{ V} + 0,05 \text{ V}$ .

###### 4.5.2.2 Anti alias filtering for digital systems

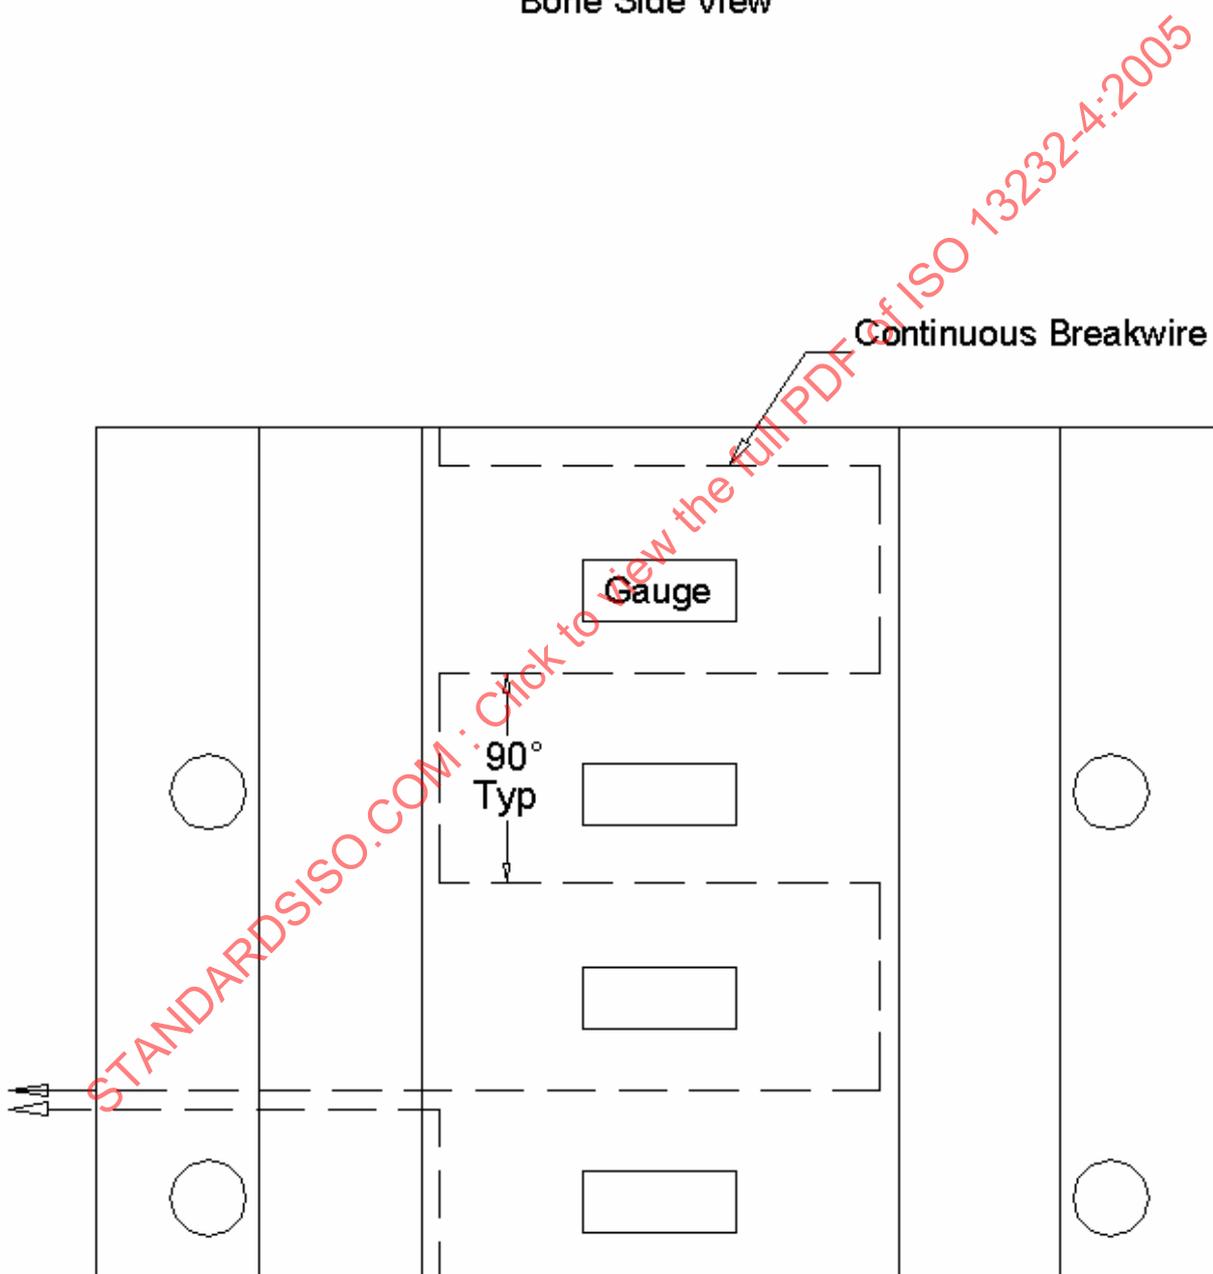

All analog data channels shall be filtered before digitizing such that the data is attenuated by at least 40 dB above a frequency of 7 kHz.

---

8) A list describing one or more example products which meet these requirements is maintained by the ISO Central Secretariat and the Secretariat of ISO/TC 22/SC 22. The list is maintained for the convenience of users of ISO 13232 and does not constitute an endorsement by ISO of the products listed. Alternative products may be used if they can be shown to lead to the same results.

Continuous Breakwire

Bone Flat Pattern  
Pattern

Figure 5 — Frangible bone break continuity sensor end-to-end wire pattern

#### 4.5.2.3 Analog to digital conversion specifications for digital systems

The analog to digital conversion specifications shall be as given in Table 3.

**Table 3 — A to D specifications for digital systems**

Parameter	Specification
Minimum number of channels	32
Minimum sampling rate	10 000 per s per channel
Maximum inter-channel slew	$12,5 \times 10^{-6}$ s
Minimum number of bits	8
Gain sensitivity to temperature	$\pm 2\%$ over the range of $0^{\circ}$ C to $70^{\circ}$ C

#### 4.5.2.4 Storage capacity

The minimum recording time capacity shall be 3,1 s.

#### 4.5.2.5 Mechanical specifications for the internal data acquisition system

The system shall be dimensioned to fit inside the thoracic spine box and/or the modified sit/stand pelvis, described in ISO 13232-3. The upper torso and lower torso component masses and centres of gravity shall be as specified in ISO 13232-3. The system shall remain operational in all axes when subjected to a 60 g peak and 0,011 s duration haversine pulse.

#### 4.5.2.6 Scaling of variables

For each recorded variable, the recorder channel gain shall be adjusted such that the minimum recording range corresponds to the value given in Table 4. The actual recording range may exceed that shown in Table 4 if the actual recorder resolution including noise (i.e., 10 bits) will result in the same or better signal resolution than that resulting from an 8 bit recorder and the minimum recording range shown in Table 4.

Table 4 — Full-scale recording ranges

Body region	Injury assessment variable	Range
Head	$a_1, a_4, a_7$ $a_3, a_6$ $a_5, a_9$ $a_2, a_8$	$\pm 400$ g
Upper neck	$F_{x,n}, F_{y,n}$ $F_{z,n}$ $M_{x,n}$ $M_{y,n}$ $M_{z,n}$	$\pm 15$ kN $\pm 30$ kN $\pm 700$ N·m $\pm 1000$ N·m $\pm 700$ N·m
Chest	$l_{uL}, l_{uR}$ $l_{lL}, l_{lR}$	$\pm 60$ mm
Lumbar spine	$F_{x,l}, F_{y,l}$ $F_{z,l}$ $M_{x,l}, M_{y,l}$ $M_{z,l}$	$\pm 5$ kN $\pm 10$ kN $\pm 500$ N·m $\pm 250$ N·m
Upper femur	$F_{z,uF}$ $M_{x,uF}, M_{y,uF}$ $M_{z,uF}$	$\pm 12$ kN $\pm 600$ N·m $\pm 400$ N·m
Lower femur	$F_{z,lF}$ $M_{x,lF}, M_{y,lF}$ $M_{z,lF}$	$\pm 12$ kN $\pm 500$ N·m $\pm 300$ N·m
Upper tibia	$M_{x,uT}, M_{y,uT}$ $M_{z,uT}$	$\pm 400$ N·m $\pm 200$ N·m
Lower tibia	$F_{z,lT}$ $M_{x,lT}, M_{y,lT}$	$\pm 40$ kN $\pm 400$ N·m

#### 4.6 High speed photography

##### 4.6.1 Camera specifications

The cameras, lenses, camera locations, lines of sight, and aim points shall be the same for all tests in a paired comparison.

The following shall be documented for each camera:

- the camera x, y, z locations relative to the targetted OV contact point, as defined in Figure 1 of ISO 13232-2, as expected at first MC/OV contact, projected to ground level and using the axis conventions defined in ISO 13232-8, A.6.5.1;
- the lens focal length;
- the approximate centre point of the field of view.

#### 4.6.2 Required cameras

All cameras used for trajectory and velocity analysis shall have a 100 Hz minimum internal timing light visible in the field of view at all times.

The cameras shall have open shutter duration times which limit the blur of the dummy helmet to a maximum of 0,020 mm, at pre-impact velocity. For example, the required maximum open shutter duration time for a film image width of 10 mm, object width of 5 000 mm, and velocity of 15 000 mm/s is 0,00067 s.

The required cameras and their specifications shall be as given in Table 5. The recommended fields of view and minimum focal lengths shall be as defined in Table B.1 of Annex B. If high speed photographic cameras are used, they should use 16 mm film. Larger film formats may be used, in which case the minimum focal lengths listed in Table B.1 shall be increased by the ratio of the larger film format to 16 mm.

#### 4.6.3 Recommended cameras

The following cameras should be used to provide additional observation capabilities:

- MC oblique view (field of view as appropriate);
- MC front view, if applicable (see Table 5 for field of view);
- OV front or rear view (5 m wide field of view);
- OV side view (8 m wide field of view);
- MC side view, if MC front or rear is used for motion analysis for impact condition 143 (field of view as appropriate).

The fields of view for these cameras should be such that the dummy head is visible in the frame from at least 0,100 s before to 0,500 s after first MC/OV contact. A wider field of view may be used to evaluate overall dynamics of the impact sequence.

#### 4.7 Still photography

Photographs or other high-resolution image recordings for use in dummy position verification shall be taken after the MC has been placed in its launch position and within 0,100 s before first MC/OV contact.

If a still photographic camera is used, the film size shall be at least 35 mm. The shutter speed setting shall be 1/500 s or faster. The minimum focal lengths and fields of view for 35 mm film shall be as given in Table 6. Larger film formats may be used, in which case the minimum focal lengths listed in Table 6 shall be increased by the ratio of the larger film format to 35 mm.

Table 5 — Required cameras and specifications

Camera view	Frame rate f/s	Camera field of view	Line of sight	Subjects at expected first MC/OV contact
MC top	400, minimum	Given in Annex B	Perpendicular to ground	Dummy helmet, first MC/OV contact point, OV, MC and ground targets
MC side, on side giving most unobstructed view of helmet trajectory (except for impact condition 143)	400, minimum	Given in Annex B	Perpendicular to pre-impact path of MC	Dummy helmet, first MC/OV contact point, OV, MC and ground targets
MC rear or front for impact condition 143	400 minimum	Given in Annex B	Perpendicular to pre-impact path of OV	Dummy helmet, first MC/OV contact point, OV, MC and ground targets
MC rear or front, as appropriate	400, minimum	Vertical, 30% ± 10% larger than overall MC/ dummy height at expected first MC/OV contact	Within 5° of parallel to pre-impact path of MC	MC and ground targets, dummy helmet
OV side, if OV speed is determined photographically	400, minimum	Given in Annex B	Perpendicular to pre-impact path of OV	OV and ground targets

**Table 6 — Still photograph minimum focal lengths and field of view widths**

View	Minimum focal length mm	Field of view width m
Side	100	4
Top	50	4

Alternative high resolution imaging systems, such as digital still or high speed video cameras, may be used if the user demonstrates that the system resolution, shutter speed, and field of view will enable the user to measure full-scale target locations, with a standard deviation of 0,25 cm or less (i.e., a total error of 0,50 cm when comparing the pre-test and pre-impact images). For a given test series, documentation of this demonstration shall be attached to the test reports that are specified in ISO 13232-8.

## 5 Measurement methods

### 5.1 Pre-test measurements related to data reduction

For each ground target, measure the x, y, z locations relative to the targetted OV contact point, as defined in Figure 1 of ISO 13232-2, as expected at first MC/OV contact, projected to ground level and using the axis conventions defined in ISO 13232-8, A.6.5.1.

Before the impact test, measure the following:

- distance between the photo-optic or electro-mechanical contact switches;
- OV overall width.

If the high speed camera lens focal length is less than that specified in Table B.1, record a grid pattern with each required high speed camera, prior to each impact test, on the same film as the impact test footage, using a grid of targets equally spaced throughout the camera field of view.

### 5.2 Data reduction

#### 5.2.1 Electronic data

Define the time when first MC/OV contact is electronically sensed to be time zero,  $t = 0,000$  s. Define data zero to be the average of the first 0,010 s of data, beginning 0,050 s before time zero. Convert the data to scaled data in physical units, using data zero and retaining three significant figures. Filter the data such that the overall frequency response of data output to unfiltered analog input is in accordance with ISO 6487 and the frequency response classes are as given in Table 7.

**Table 7 — Motorcyclist anthropometric impact dummy frequency response classes**

Typical test measurements	Frequency response class
Head linear accelerations	1000
Neck	
Forces	1000
Moments	600
Thorax	
Deflections	180
Lumbar	
Forces	1000
Moments	1000
Femur/tibia	
Forces	600
Moments	600

Separate the data into windows identified as primary or secondary impact periods.

Store the data in electronic files which are compatible with the latest version of ISO 13499.

Calculate the head linear accelerations,  $a_{x,H}$ ,  $a_{y,H}$ , and  $a_{z,H}$ , and the head angular accelerations,  $\alpha_{x,H}$ ,  $\alpha_{y,H}$ , and  $\alpha_{z,H}$ , over time, using the program which is included in Annex C.

Calculate neck occipital condyle moments using the procedures given in SAE J1733.

**5.2.2 Calibration of frangible leg bone strain gauges**

Calibrate each frangible bone strain gauged variable using the procedure described below.

**5.2.2.1 Load application**

Apply the following loads to the bone, one at a time, as shown in the corresponding figures:

- $F_z = 3\,000\text{ N}$ , as shown in Figure 6;
- $M_x = 20\text{ N}\cdot\text{m}$ , as shown in Figure 7;
- $M_y = 20\text{ N}\cdot\text{m}$ , as shown in Figure 7;
- $M_z = 10\text{ N}\cdot\text{m}$ , as shown in Figure 8.

**5.2.2.2 Record data**

For each of the four applied loads and each strain gauge data channel planned to be used during a crash test, record the following information in Table 8, 9, or 10:

- excitation voltage;

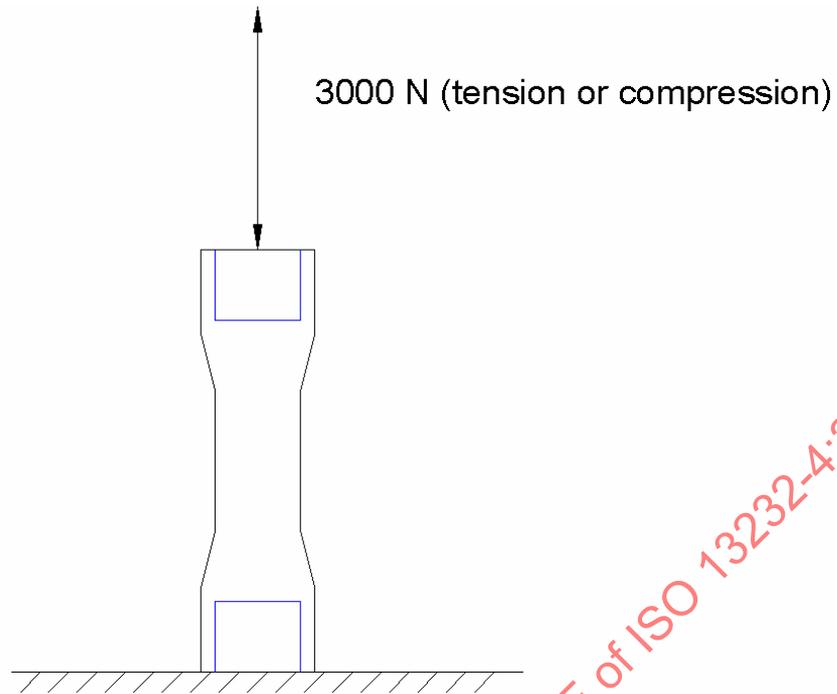

Figure 6 —  $F_z$  strain gauge calibration

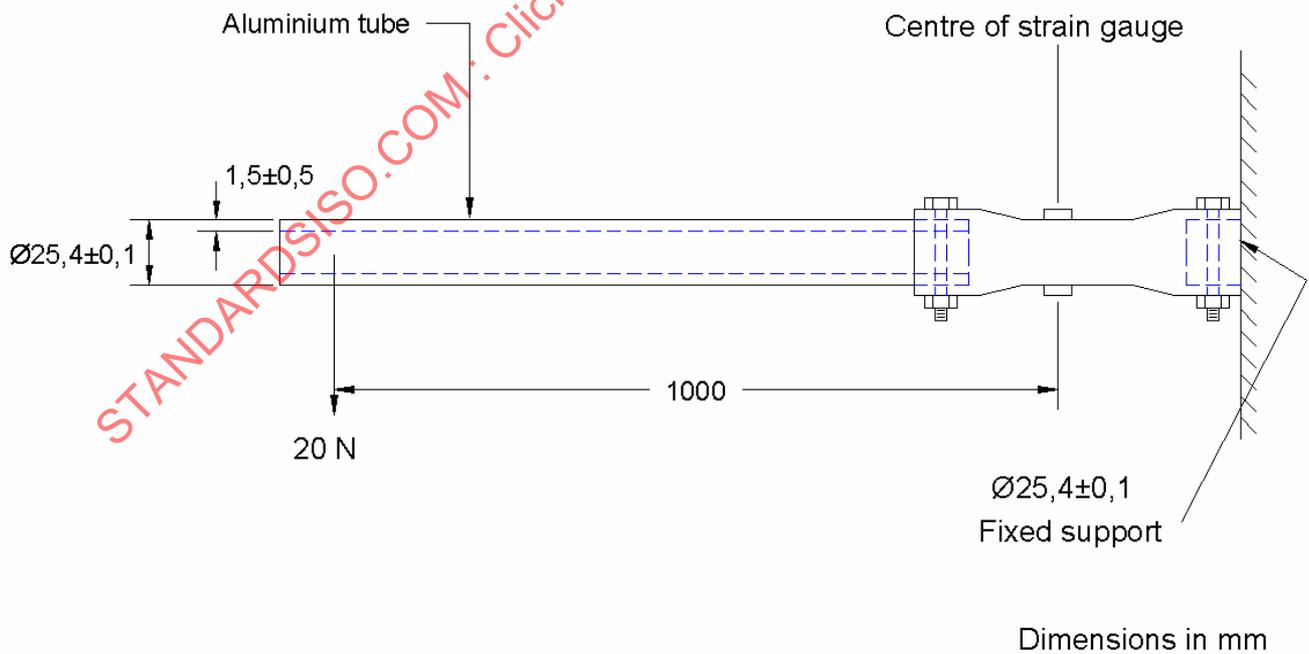

Figure 7 —  $M_x$  and  $M_y$  strain gauge calibration

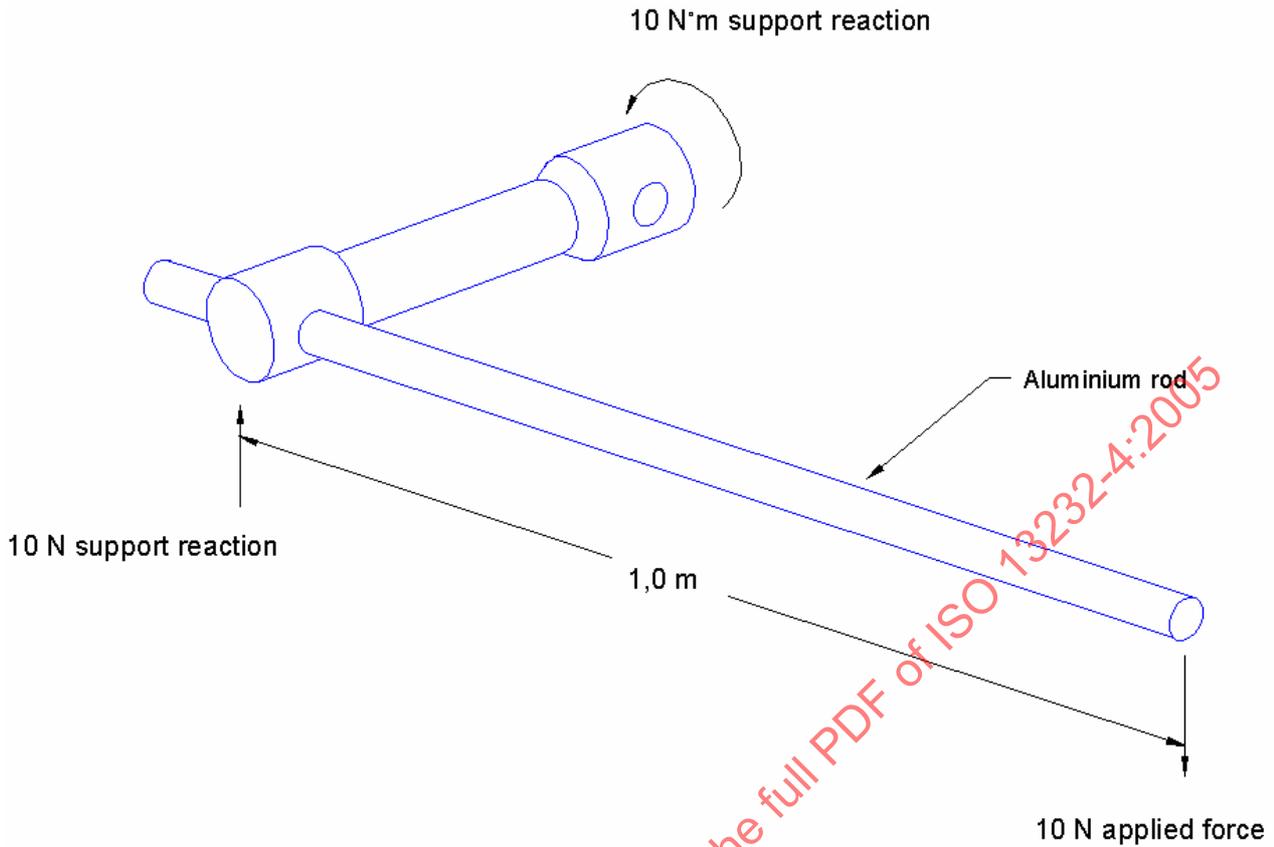

Figure 8 —  $M_z$  strain gauge calibration

- signal gain used for the calibration procedure (may be different than the signal gain used during a full-scale impact test);
- the change in output signal voltage which is caused by the application of each respective load.

Select a signal gain such that the signal-to-noise ratio as calculated in 5.2.2.3 is 250 or more. Record all off axis signals for each applied load and for each data channel to be recorded in the full-scale test. If a specific data channel is not to be recorded in the full-scale test, enter "N.A." (not applicable) in the corresponding row of Table 8, 9, or 10.

### 5.2.2.3 Sensor primary sensitivity

For each data channel, calculate and enter into Table 8, 9, or 10 the sensor primary sensitivity per volt of excitation, using the applied load and resulting change in output signal voltage for the primary axis of the sensor, as shown in the following example equations:

$$\text{Primary sensitivity} = \Delta E_0 / E_e L \text{ Gain}$$

where

primary sensitivity is in volts per newton per volt or volts per newton-meter per volt;

$\Delta E_0$  is the change in output signal voltage, in volts;

**Table 8 — Calibration data for femur strain gauges**

Bone identification \_\_\_\_\_

Excitation voltage \_\_\_\_\_

Data channel	Signal gain	Change in output signal voltage for applied load				Primary sensitivity
		$F_z$ at 3 000 N	$M_x$ at 20 N·m	$M_y$ at 20 N·m	$M_z$ at 10 N·m	
Femur $F_z$						a
Femur $M_x$						b
Femur $M_y$						b
Femur $M_z$						b
	Denotes primary voltage change, used to calculate primary sensitivity.					
<p><sup>a</sup> Expressed in volts of output per newton per volt of excitation.</p> <p><sup>b</sup> Expressed in volts of output per newton-meter per volt of excitation.</p>						

**Table 9 — Calibration data for upper tibia strain gauges**

Bone identification \_\_\_\_\_

Excitation voltage \_\_\_\_\_

Data channel	Signal Gain	Change in output signal voltage for applied load				Primary sensitivity
		$F_z$ at 3 000 N	$M_x$ at 20 N·m	$M_y$ at 20 N·m	$M_z$ at 10 N·m	
Upper tibia $M_x$						a
Upper tibia $M_y$						a
Upper tibia $M_z$						a
	Denotes primary voltage change, used to calculate primary sensitivity.					
<p><sup>a</sup> Expressed in volts of output per newton-meter per volt of excitation.</p>						

**Table 10 — Calibration data for lower tibia strain gauges**

Bone identification \_\_\_\_\_

Excitation voltage \_\_\_\_\_

Data channel	Signal Gain	Change in output signal voltage for applied load				Primary sensitivity
		$F_z$ at 3 000 N	$M_x$ at 20 N·m	$M_y$ at 20 N·m	$M_z$ at 10 N·m	
Lower tibia $F_z$						a
Lower tibia $M_x$						b
Lower tibia $M_y$						b
	Denotes primary voltage change, used to calculate primary sensitivity.					
<p><sup>a</sup> Expressed in volts of output per newton per volt of excitation.</p> <p><sup>b</sup> Expressed in volts of output per newton-meter per volt of excitation.</p>						

$E_e$  is the excitation voltage, in volts;

$L$  is the applied load, in newtons or Newton  $\cong$  meters;

Gain is the gain of the amplifier used during calibration.

$$S/N = \Delta E_0 / Acc_{mtr}$$

where

S/N is the signal-to-noise ratio;

$\Delta E_0$  is the change in output signal voltage, in volts;

$Acc_{mtr}$  is the accuracy of the meter.

If any off axis output signal voltages for a channel as listed in Tables 8, 9, or 10 exceed 15% of the primary voltage change for that channel, do not use that strain gauge data channel in a full-scale impact test.

If strain gauges are used in the full-scale impact tests, include Tables 8, 9, and 10, as applicable, in ISO 13232-8.

**5.2.3 Frangible component data**

Any loss of a dummy leg due to failure of the retaining cables shall be noted in the test documentation according to ISO 13232-8.

Disassemble the dummy. Inspect the frangible components. Photograph them against a contrasting background, at a scale which clearly indicates any fractures or deformations, and so that the test number clearly shows. If any off axis output signal voltages for a channel as listed in Tables 8, 9, or 10 exceed 15% of the primary voltage change for that channel, do not use that strain gauge data channel in a full-scale impact test.

If strain gauges are used in the full-scale impact tests, include Tables 8, 9, and 10, as applicable, in ISO 13232-8.

### 5.2.3.1 Tibia and femur bones

Determine the severity of damage to the frangible leg bones. A leg bone is considered fractured if the ends of the bone can be rotated relative to one another by manual means. Otherwise, it is considered to be not fractured. For a fractured bone, if the fractured bone pieces are placed in their initial unfractured relative positions, and if the fractured regions are more than 20 mm in axial extent, then the fracture is considered to be a displaced fracture. Otherwise, the fracture is considered to be a non-displaced fracture.

### 5.2.3.2 Knee torsional and varus valgus shear pins

Determine the severity of damage to each frangible knee joint. For each frangible knee, if one shear pin is fractured into two or more separate pieces, then the knee is considered to be partially dislocated. For each frangible knee, if two shear pins are fractured into two or more separate pieces, then the knee joint is considered to be completely dislocated. Otherwise, the knee is considered to be not dislocated.

### 5.2.3.3 Abdominal insert

Measure the maximum residual deformation depth of the abdominal insert material in the direction of abdominal crush, relative to the undeformed surface. This is considered to be the abdomen maximum residual penetration,  $P_{A,max}$ .

## 5.2.4 High speed photographic image data from required cameras

### 5.2.4.1 Time base analysis

Establish the first visible MC/OV contact or the last frame prior to emission of the contact sensor light, whichever is sooner. Analyse the data at the frame intervals given in Table B.1. Using the camera timing lights, calculate the time associated with each analysed film frame, from 10 film analysis frames before first MC/OV contact until 10 analysis frames after first helmet/OV contact or until 80 analysis frames after first MC/OV contact or until the helmet centroid leaves the field of view, whichever is sooner.

### 5.2.4.2 Helmet trajectory analysis

Using the procedures described in Annex A, digitize the helmet centroid point position for every Nth film frame. Calculate N using the equation given below, then round up to the nearest integer value.

$$N = \frac{0,012W_f x r_f}{V_{x,MC,p}}$$

where

$N$  is the film frame;

$W_f$  is the frame width, in metres;

$r_f$  is the frame rate, in frames per second;

$V_{x,MC,p}$  is the pre-impact velocity of the MC (or the OV for stationary MC tests), in metres per second;

0,012 is a constant which provides a signal-to-noise ratio of 6, given a film frame resolution of 0,2 percent of  $W_f$ .

Examples of film analysis intervals are given in Table B.1.

Digitize the helmet centroid point for the time frame defined in 5.2.4.1 using the following procedure:

**5.2.4.2.1** Set  $x_h = y_h = 0$  at first MC/OV contact, and  $z_h$  to be the  $z$  coordinate of the helmet centroid relative to the ground at first MC/OV contact, with  $z_g = 0$ .

**5.2.4.2.2** Digitize and calculate the value of each helmet centroid point position relative to a fixed ground target, in order to eliminate the effects of camera framing variations. For all impact configurations except 143, digitize the  $y_h$  position using the MC top view camera, and digitize the  $x_h$  and  $z_h$  positions using the MC side view camera. For impact condition 143 digitize the  $x_h$  position using the MC top view camera, and digitize the  $y_h$  and  $z_h$  positions using the MC front or rear view camera.

NOTE This helmet trajectory analysis procedure is currently not very meaningful for impact configuration 143. It is intended that a future revision of ISO 13232 will address this issue.

**5.2.4.2.3** Calculate  $x_h$ ,  $y_h$ , and  $z_h$  using a depth correction factor. For example, for  $x_h$ :

$$x_h = x_{h,g} \times \frac{d_{c,h}}{d_{c,g}}$$

where

$x_h$  is the depth corrected inertial  $x$  position of the helmet centroid point;

$x_{h,g}$  is the apparent inertial  $x$  position of the helmet centroid point relative to the ground fixed target;

$d_{c,h}$  is the perpendicular distance between the camera and the helmet centroid point, as calculated from measurements defined in 4.6.1 and the test layout geometry sketched in ISO 13232-8, A.6.5.1, in metres;

$d_{c,g}$  is the perpendicular distance between the camera and the ground fixed targets described in 4.3.4, as calculated from measurements defined in 4.6.2 and the test layout geometry sketched in ISO 13232-8, A.6.5.2, in metres.

**5.2.4.2.4** Calculate the time associated with each analysis frame, using the camera timing light according to 5.2.4.1.

**5.2.4.2.5** If the lens focal length is less than that specified in Table B.1, correct the positions for lens distortion by using a grid of targets, as specified in 5.1.

**5.2.4.2.6** Smooth the positions using four passes of a moving average filter:

$$x_{h,l} = \frac{x_{h,i-1} + 2x_{h,i} + x_{h,i+1}}{4}$$

where

$x_{h,i}$  is the helmet centroid point position for analysis frame  $i$ , in metres.

## 5.3 Impact conditions

### 5.3.1 MC and OV impact speeds

Determine the distance travelled by the vehicle and the elapsed time required to travel that distance in order to calculate the vehicle speed using either the film analysis method or electronic method described below.

#### 5.3.1.1 Film analysis method

Use the high speed MC and OV side cameras with the narrow view.

### 5.3.1.1.1 Distance

On the film digitizing surface, scale the distance between the two ground targets based on the previously measured actual distance, as measured in 5.1. Using this scale, locate the position of the vehicle target with respect to a single ground target in the film frames up to but not including, first MC/OV contact. Calculate the actual distance travelled by the vehicle target using a depth correction factor, according to 5.2.4.2.3, and such that the minimum distance travelled by the vehicle target during the measurement interval exceeds 1,0 m.

### 5.3.1.1.2 Elapsed time

Calculate the elapsed time over the measurement interval, using the film frame count at 1 000 fps. Multiply the elapsed time by the frame time correction, determined by the camera timing light.

### 5.3.1.2 Electronic method

#### 5.3.1.2.1 Distance

Use two photo-optic or electro-mechanical contact switches located more than 1,0 m apart, and positioned immediately before the first MC/OV contact point. Record the electronic pulses on an electronic recording device which has an encoded time base and a maximum time base error of 0,001 s.

#### 5.3.1.2.2 Elapsed time

Calculate the elapsed time, the difference in pulse times, measured with the electronic recording device.

### 5.3.2 Relative heading angle at impact

Use the film from the overhead, narrow view, high speed camera. Analyse the frame immediately preceding the first MC/OV contact. Draw a line connecting the MC front and rear centre line targets and draw another line connecting any two of the OV bonnet or boot lid centre line targets, or alternatively a line connecting the two OV roof centre line targets. Measure the angle clockwise from the MC centre line to the OV centre line.

### 5.3.3 MC roll angle at impact

Use the ground based vertical reference targets and the film from either the MC rear or the MC front view camera. Analyse the film frame immediately preceding the first MC/OV contact. Using either the front or rear tyre centre line, or a line connecting the upper and lower MC centre line targets, measure the angle between the ground based vertical reference and the MC vertical centre line reference.

### 5.3.4 OV contact point

Use the film from the overhead, narrow view, high speed camera. Analyse the film frame immediately preceding the first MC/OV contact.

If the OV contact point is the front, front corner, rear, or rear corner, and the MC contact point is the front or rear, then the OV contact point lateral distance ( $y_{cp}$ ) is considered to be the distance, in metres, between the OV and MC centre lines, measured perpendicularly to the OV centre line, at the OV leading edge. See Figure 9a.

If the OV contact point is the side, calculate the OV contact point longitudinal distance ( $x_{cp}$ ) as shown in Figure 9b, using the following equation:

$$x_{cp} = [(W_{OV} / 2) \tan(90 - rha)] + a$$

where

$x_{cp}$  is the OV contact point longitudinal distance, in metres;

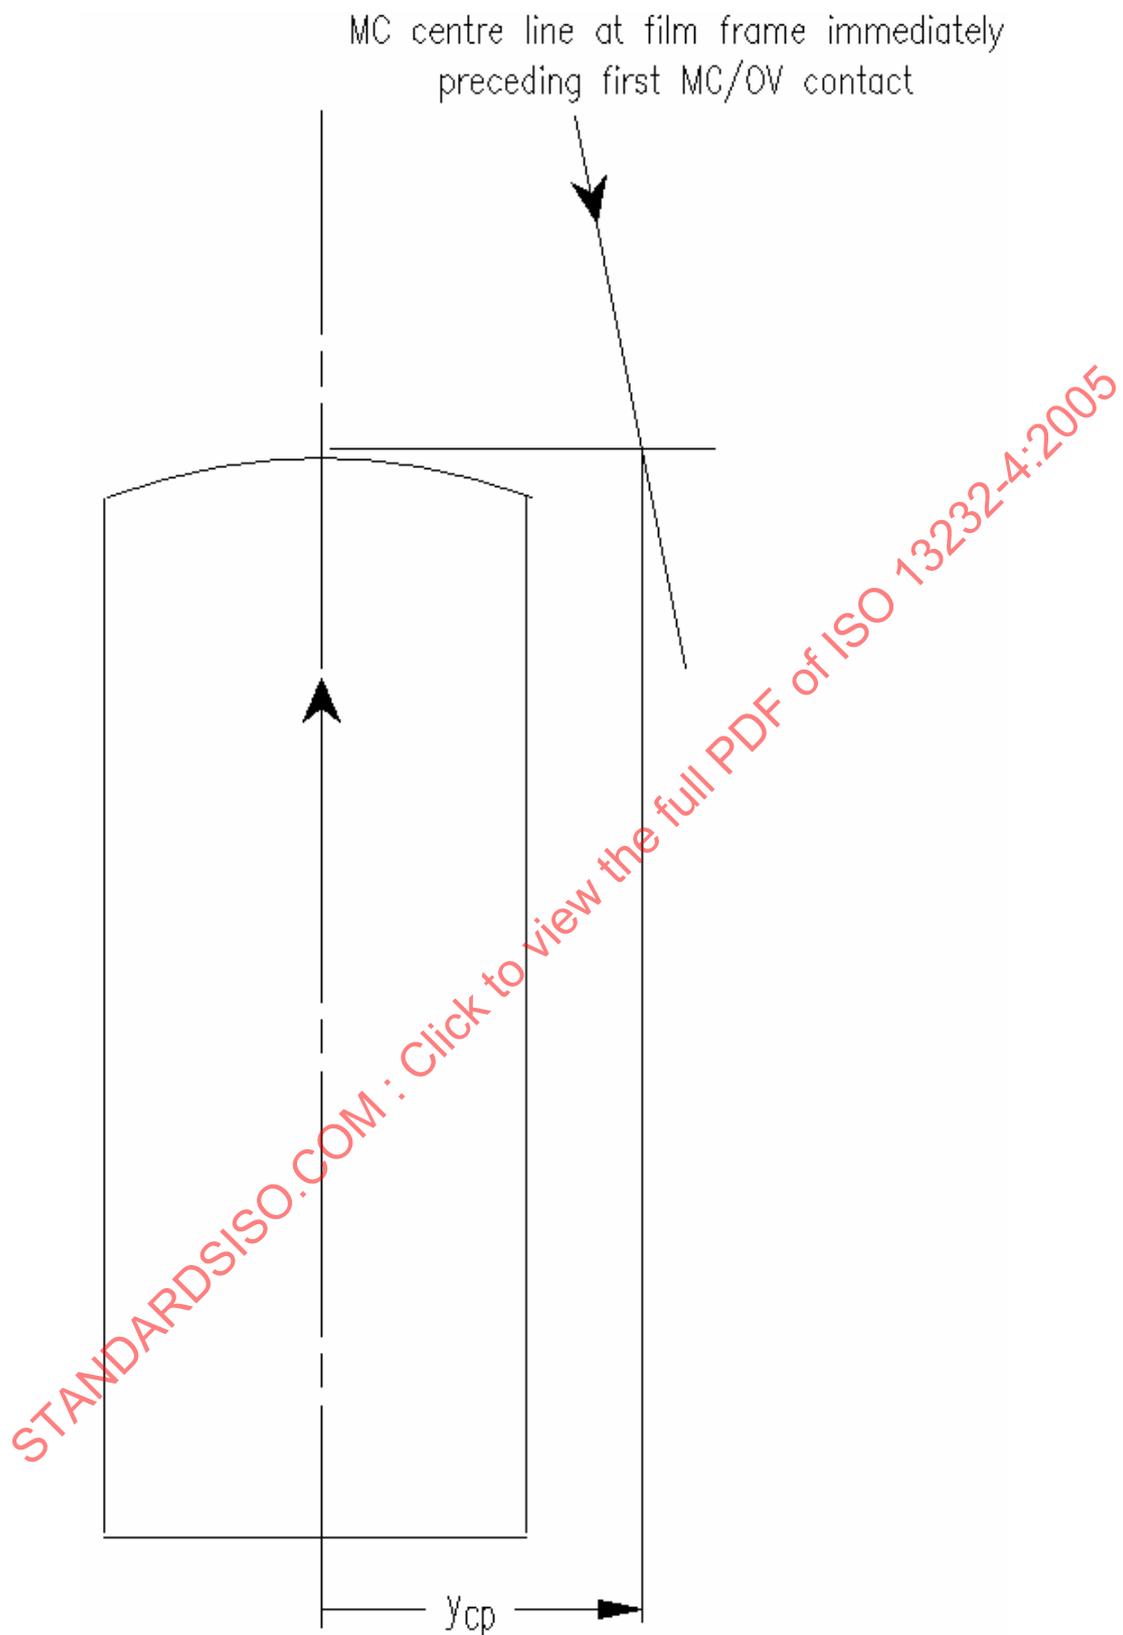

Figure 9a — OV contact point determination for OV front, front corner, rear, or rear corner contact with MC front or rear contact

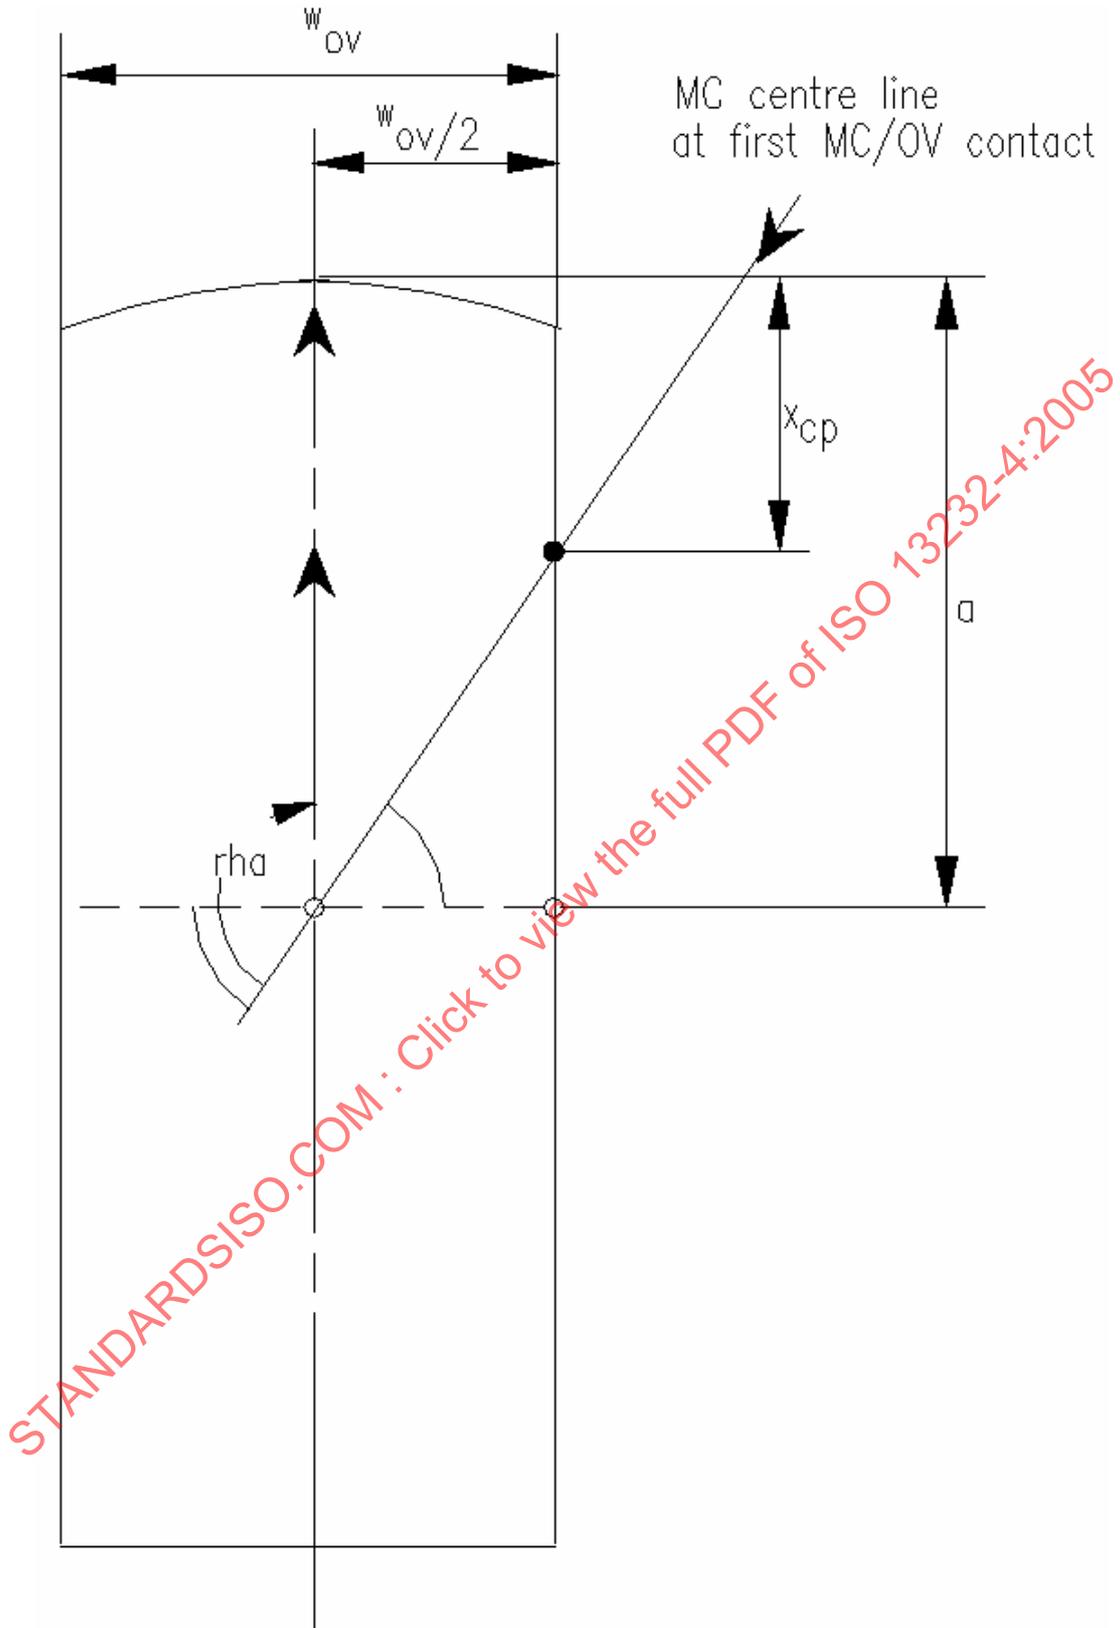

Figure 9b — OV contact point determination for OV side contact

$W_{OV}$  is the OV overall width, in metres;

$r_{ha}$  is the relative heading angle, in degrees;

$a$  is the distance between the OV leading edge and the intersection of the OV and MC centre lines, in metres.

If the OV contact point is the front or rear and the MC contact point is the side, then  $y_{cp}$  is the distance, in metres, between the OV centre line and the mid-point along the overall length of the MC. See Figure 9c.

### 5.3.5 Dummy position verification

Use the pre-test and pre-impact top and side view images.

From the side view images, record the relative  $x$  and  $z$  positions of the dummy helmet centroid and the shoulder, hip, knee, and ankle points with respect to the motorcycle targets. From the top view images, record the relative  $x$  and  $y$  position of the dummy helmet centroid with respect to the motorcycle targets. If a portion of the motorcycle or other object obscures one or more of these points, record the positions of the remaining points.

## 5.4 Frangible bone continuity sensors

### 5.4.1 Wire mounting

Bond a continuous length of  $0,17 \text{ mm} \pm 0,02 \text{ mm}$  diameter magnet wire to the frangible bone with a cyanoacrylate based adhesive. Use an end-to-end wire pattern, as shown in Figure 5 which results in at least four sections of wire running the length of the bone, spaced no more than  $90^\circ$  from each other. An accelerant compound may be used to cure the adhesive.

Solder the two ends of the  $0,17 \text{ mm}$  wire to a multi strand wire with a total diameter of  $0,49 \text{ mm} \pm 0,05 \text{ mm}$ , which is terminated with a small connector. Tape the  $0,49 \text{ mm}$  wire to the bone in such a way as to protect the  $0,17 \text{ mm}$  wire.

Check continuity of each  $0,17 \text{ mm}$  wire to ensure that it was not broken during the assembly process.

### 5.4.2 Sensor unit

Assemble a sensor unit as shown in Figure 10. Configure reusable portion of the sensor to be compatible with the data acquisition system and the small bone connectors, described above.

Check the function of the sensor by connecting and disconnecting the various bone connectors while monitoring the output signal. Document the relationship between broken wires and the resulting signal for post test data analysis.

## 6 Documentation

All specification, calibration, and test data described above shall be documented in accordance with ISO 13232-8.

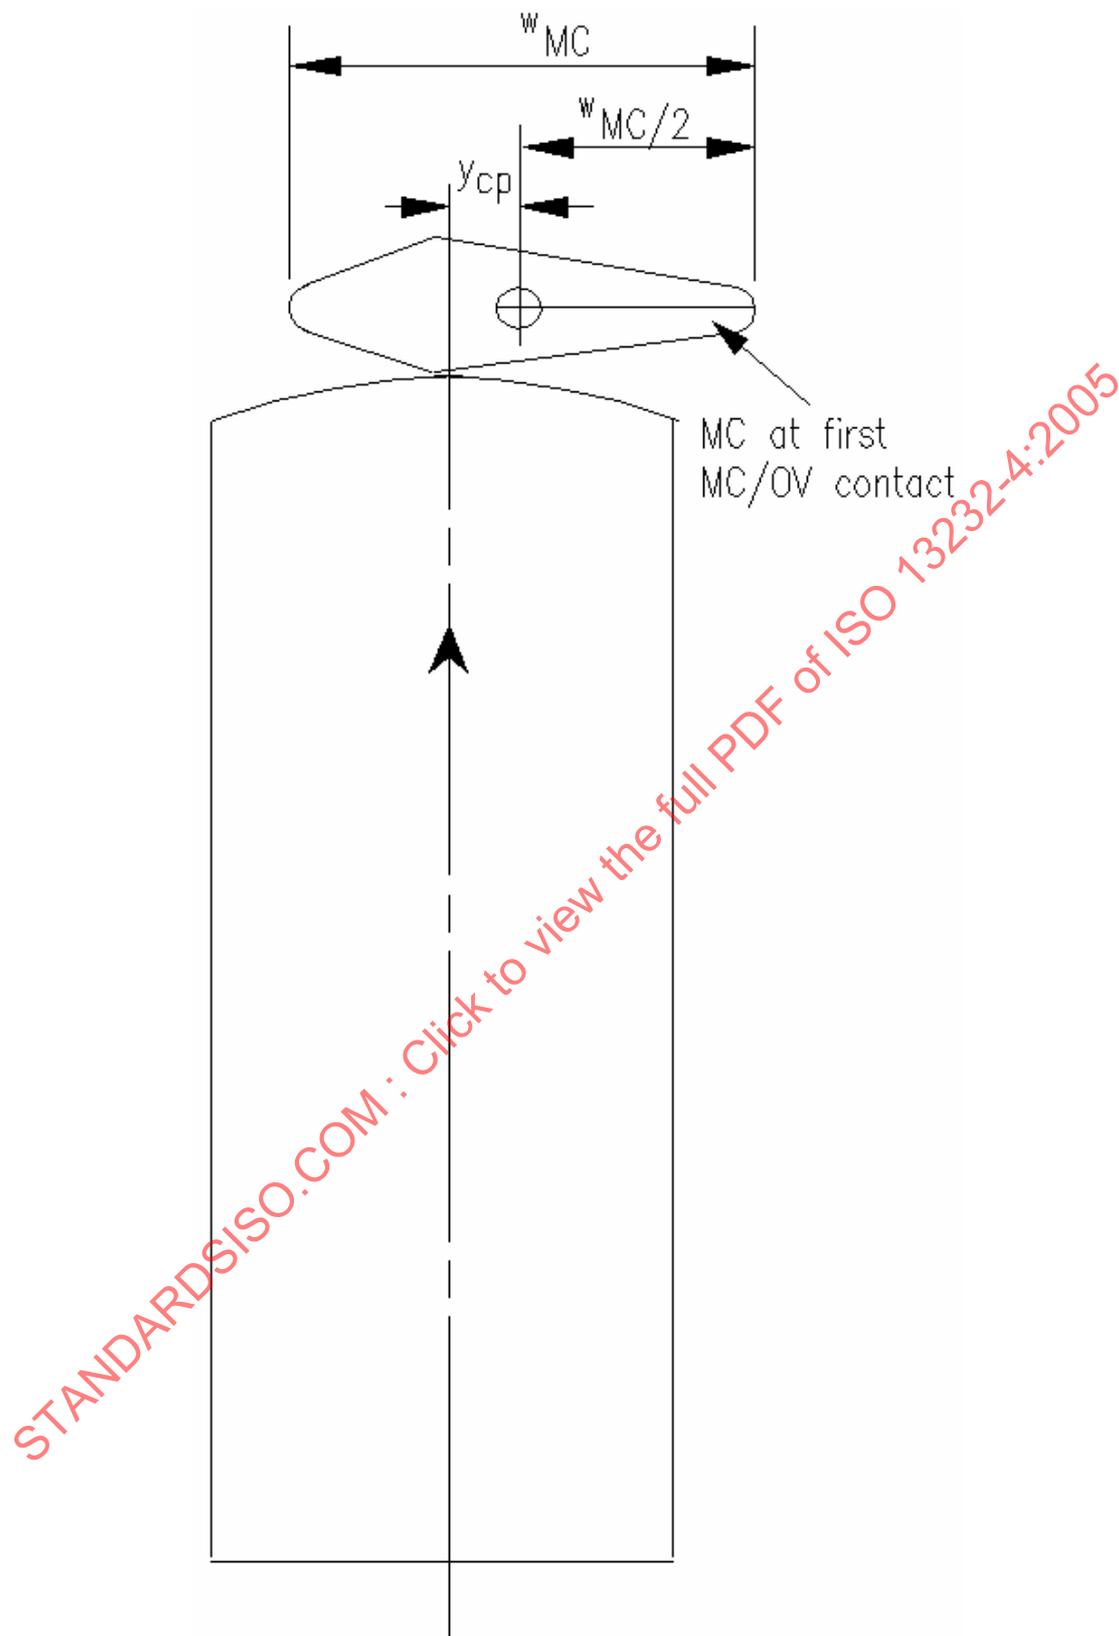

Figure 9c — OV contact point determination, OV front or rear contact with MC side contact (positive  $y_{cp}$  shown)

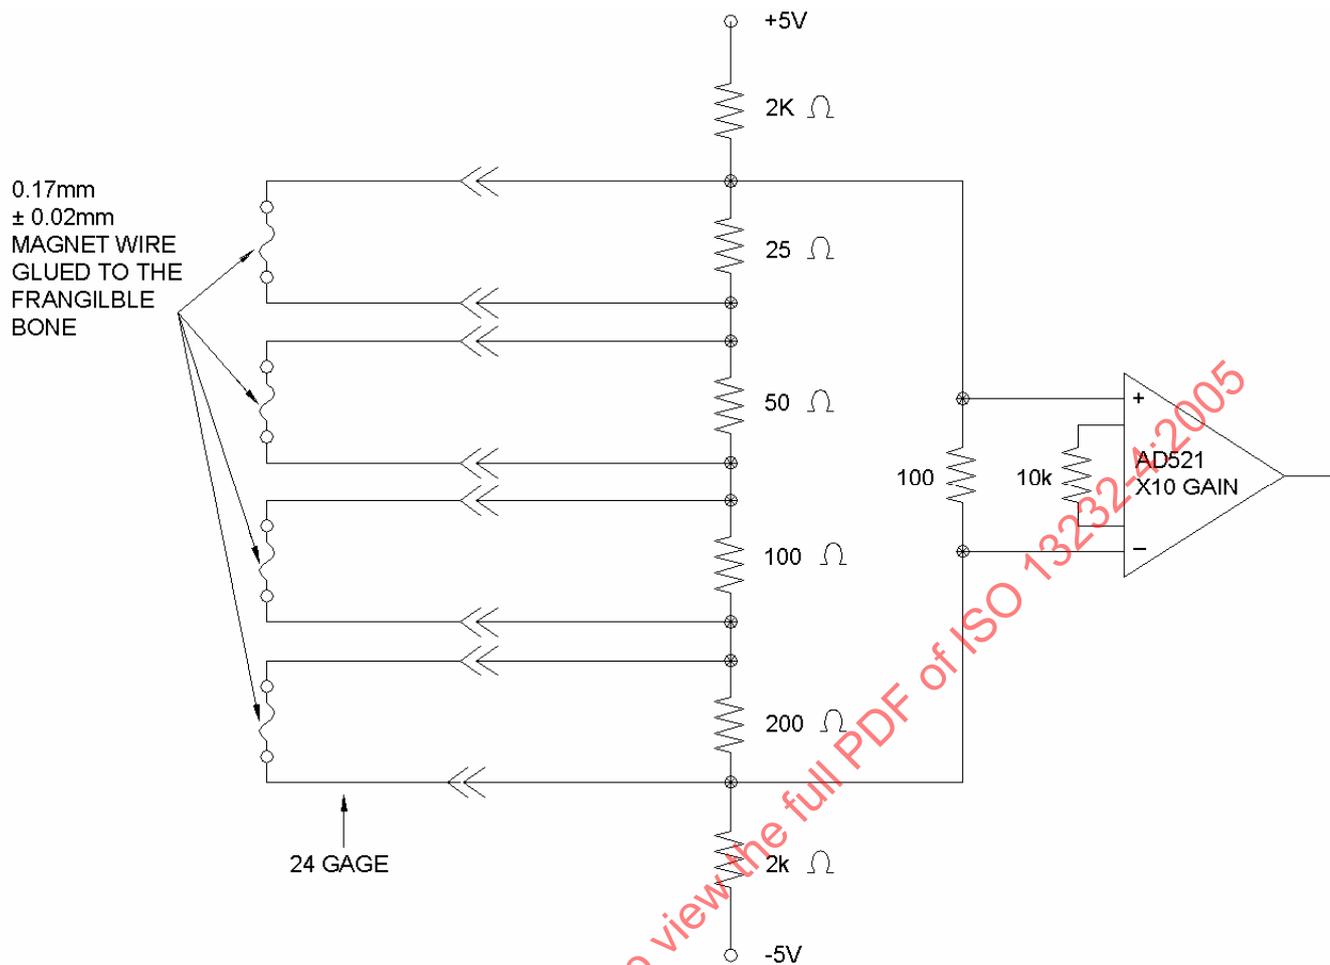

Figure 10 — Frangible bone continuity sensor circuit

## Annex A (normative)

### Digitizing the helmet centroid point

#### A.1 Principle

Identification and digitization of helmet centroid point using the MC top and side view cameras.

#### A.2 Apparatus

Film motion analyser, as specified in 4.3.

#### A.3 Procedure

- A.3.1 Load the film in the film analyser.
- A.3.2 Set the film to the frame when first MC/OV contact occurs.
- A.3.3 Overlay a transparent film on the digitizing surface.
- A.3.4 Draw a circle which circumscribes the helmet as seen on the digitizing surface.
- A.3.5 Mark the centre of the circle. This is the helmet centroid point.
- A.3.6 For each analysis frame, centre the circle about or within the helmet, using the visible portion of the helmet outline, by moving the transparent film around on the digitizing surface.
- A.3.7 Digitize the location of the circle centre mark.

## Annex B (normative)

### High speed photography field of view requirements

#### B.1 Seven impact configurations for MC top and side views

For the seven impact conditions listed in Table B.1, the field of view should be as listed. For typical 16 mm high speed cameras, the minimum lens focal length should be as listed in Table B.1. If shorter lens focal lengths are used, correction for lens distortion should be done. For the fields of view and focal lengths listed in Table B.1, the film analysis intervals should be as listed in Table B.1. For other fields of view and focal lengths the film analysis interval should be as described in 5.2.4.1.

#### B.2 Other impact configurations and other camera views

Select the camera, lens, and camera position such that the frame width is:

$$W_f = V_{x,h,p} \times 0,600 \text{ s}$$

where

$W_f$  is the frame width, in metres;

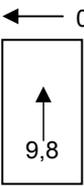

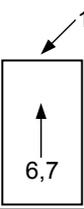

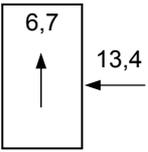

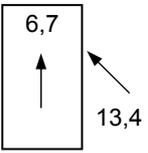

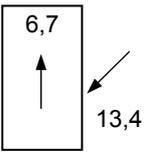

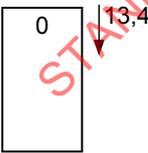

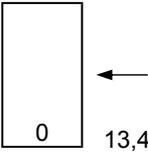

$V_{x,h,p}$  is the velocity of the pre-impact dummy helmet centroid point for the MC top or side view cameras, in metres per second;

0,600 s is the amount of time that the dummy helmet centroid point should be in the field of view.

The OV pre-impact velocity is used to determine the frame width for the OV side or top view cameras.

Narrower views may be used provided that the helmet is visible at first helmet/OV contact. Select the aim point such that the helmet is visible at least 0,100 s before first MC/OV contact. Orient the camera frame such that the frame width is aligned parallel to the pre-impact motion of the helmet. Record the camera lens focal length and  $x$ ,  $y$ ,  $z$  location with respect to expected first MC/OV contact point and ground. The film analysis interval should be as described in 5.2.4.1.

Table B.1 — Photographic specifications for seven impact configurations

Configuration m/s	Camera	Recommended camera field of view		Minimum lens focal length mm	Film analysis interval frames see NOTE
		Width m	Height m		
	Side	8,0	5,7	25	10
	Top	8,0	5,7	13	10
	Side	8,0	5,7	25	8
	Top	8,0	5,7	13	8
	Side	9,8	5,7	25	8
	Top	8,0	5,7	13	8
	Side	8,0	5,7	25	8
	Top	8,0	5,7	13	8
	Side	8,0	5,7	25	8
	Top	8,0	5,7	13	8

NOTE If the camera frame rate is not 1000 fps, multiply the given film analysis interval by ratio of the frame rate to 1000.

## Annex C (normative)

### Computer code for calculation of head linear and angular accelerations

A computer program which calculates the values of  $a_{x,H}$ ,  $a_{y,H}$ , and  $a_{z,H}$ , and  $\alpha_{x,H}$ ,  $\alpha_{y,H}$ , and  $\alpha_{z,H}$  given the nine head linear accelerations measured over time. The input head accelerations include those listed in 4.1.1.

## Annex D (informative)

### Rationale for ISO 13232-4

All references cited in Annex D are listed in Annex B of ISO 13232-1.

#### D.1 Specific portion of the Scope

The goal of this part of ISO 13232 is to provide measurement procedures and apparatus which give repeatable measurements within a test facility and reproducible measurements across test facilities. This means that, ideally, for a given impact event, repeated measurements (e.g., reanalysis of a high speed film) would yield the same results, and all laboratories would get the same results. This applies to all aspects of the measurement process, including sensor specification, calibration, recording means, camera positioning, etc.

"Dummy instrumentation" refers to the use of specific apparatus (e.g., sensors) which are physically, inertially, geometrically, and dynamically compatible with the specialized MC dummy described in ISO 13232-3, and with the expected MC impact conditions, e.g., unrestrained motions, high accelerations, and forces, etc. It also refers to, for example, the goal of not artificially distorting the motion of the MC dummy by the use of external cables; or for example, inclusion of means for electronically monitoring the forces in the frangible leg bones.

#### D.2 Requirements (see 4)

##### D.2.1 Electronically recorded variables (see 4.1)

###### D.2.1.1 Required (see 4.1.1)

**D.2.1.1.1** Nine linear accelerometers are used to measure head linear and angular accelerations, according to the method developed by Padgaonkar, et al., (1975). This involves a triaxial central sensor and three biaxial sensors aligned with each of the triaxial axes.

The nine variables from the sensors are arithmetically combined to produce three linear accelerations and three angular accelerations as described in Annex C. The six components are then combined to calculate the brain injury index as described in ISO 13232-5.

**D.2.1.1.2** Chest mid-sternum displacement relative to the thoracic spine box is recorded to enable calculation of chest compression and chest compression velocity as defined in ISO 13232-5. Left and right triangulated displacements are sensed as shown in Figure 3. This has several advantages. First, it enables installation of the frangible abdominal insert which would normally interfere with the location of the standard Hybrid III rotational potentiometer in the lower thorax. Second, placing the potentiometers on either side of the spine box allows for full travel of the sternum plate. Third, the use of separate left and right measurements allows for later analysis of asymmetric sternum displacement, although this effect is not currently included in the chest injury indices.

**D.2.1.1.3** The measurement of upper and lower displacements allows the worst values from the two injury sites to be used in calculating injury costs (see ISO 13232-5).

**D.2.1.1.4** Six neck forces and moments are recorded to enable evaluation of upper neck injuries as defined in ISO 13232-5. The forces and moments are sensed in the region of the atlanto-occipital juncture.

**D.2.1.1.5** Three upper femur forces and moments are recorded for each leg for leg protective device evaluation. These are not directly used in injury prediction but are used to help trace sources of frangible leg damage. The lateral and antero-posterior bending moments are recorded because these are the primary likely axes of femur

failure based on past tests and clinical data. The axial force is also recorded because this can contribute to potential bending failure, via the hip joint eccentricity. Shear forces are not required variables because these are less common axes of failure for the upper leg. Also, torsion moment is not required because the femur tends to be isolated in torsion by the hip ball joint and varus degree of freedom at the knee.

Two upper tibia bending moments are recorded for each leg for leg protective device evaluation and, as with the upper femur variables, are used primarily to trace sources of potential bone fracture rather than as an injury index. The lateral and antero-posterior bending moments are recorded because these are the primary likely axes of tibia failure. Additional tibia and femur forces and moments may be recorded as permissible variables, as described below.

#### **D.2.1.2 Not recommended (see 4.1.2)**

It is recommended that chest acceleration not be recorded in motorcycle impact research tests, because for distributed, three dimensional impacts, these measurements are potentially misleading and could result in erroneous conclusions. Existing chest acceleration criteria evolved from early studies of dynamic effects on injuries. Tolerance to deceleration was found to increase with decreased exposure. Chest acceleration criteria assume that the thorax acts as a rigid body subjected to whole body decelerations. The limitations associated with the application of this criterion and associated measurements include: a lack of sensitivity to impact location, i.e., accelerations registered in the thorax cannot be isolated from load paths through the knees, legs, pelvis, hips, shoulders and head; dynamic force amplification due to rigid impacts to the exposed rigid Hybrid III shoulder; the inability to account for the effect of chest deformation on injury causation; and the sensitivity of the criterion to the impact test set up.

Likewise, measurement and recording of pelvic accelerations are considered to be potentially misleading in the case of motorcycle impacts, and therefore, are not recommended. Early pelvic acceleration criteria were based on whole body motion concepts. They did not consider rigid impacts to the ischia and other pelvic structures to which motorcycle riders may be exposed; nor did they consider the gross differences in stiffness between the human pelvis and the cast aluminum Hybrid III pelvis. The human pelvis is relatively flexible, with the deflection at fracture being as much as 50 mm in some regions. The Hybrid III pelvis, on the other hand, is essentially rigid, and this results in dynamic force amplification (compared to forces on cadavers) when it is contacted by other rigid structures not typically found in car frontal impacts, but quite common in motorcycle multi-directional crashes. This force amplification is potentially misleading, and could result in erroneous conclusions.

#### **D.2.1.3 Permissible (see 4.1.3)**

The permissible variables are, in general, those variables for which injury criteria were not available at the time of the writing of ISO 13232, and/or which may supplement the required variables for purposes of tracing potential injury sources. They include: the six axes of lumbar forces and moments; and the forces and moments acting on the femur and tibia, which may be useful, for example, for tracing the sources of leg fractures.

In general, the lower femur and lower tibia variables are permissible rather than required because they are in the frangible region of the respective bones. This requires the use of strain gauges which are destroyed in the fracture event. The upper tibia sensors are also in the frangible region, but are required for leg protective device evaluation because they give some indication of loads occurring at the knee and also at the upper tibia.

#### **D.2.2 Mechanically recorded variables (see 4.2)**

As described elsewhere (for example, in the rationales for ISO 13232-3 and ISO 13232-5), because of the wide distribution of potential injuries to these body regions and the nature of the related body structures, there are currently no practical means for electronically sensing abdomen, femur, knee, and tibia injury variables over wide areas (for example, along the length and around the circumference of the tibia). The alternative used here is to model the body structures directly; to incorporate mechanical biofidelity up to and including failure; and then to record the failures (i.e., deformation or fracture occurrence) as direct measures of injury potential.

### D.2.3 Photographic targets to be digitized (see 4.3)

Targets are to be digitized at first MC/OV contact for the OV and top, rear, and front MC targets in order to enable measurement and verification of the impact conditions, the tolerances for which are described in ISO 13232-6.

#### D.2.3.1 Helmet centroid point (see 4.3.1)

The helmet centroid point is needed to measure helmet trajectory and helmet velocity at contact with the OV, which are the two injury potential variables described in ISO 13232-5.

#### D.2.3.2 Motorcycle (see 4.3.2)

The motorcycle top, and rear, or front view centre lines are needed to measure initial motorcycle roll and relative heading angle. The main frame front or rear reference targets are needed for a time history in order to calculate MC speed just before impact.

#### D.2.3.3 Opposing vehicle (see 4.3.3)

The OV bonnet, roof, and boot lid centre lines are needed in order to measure and calculate the relative heading angle and the initial OV contact point. The body side reference time history is needed in order to calculate OV speed just prior to impact.

#### D.2.3.4 Ground (see 4.3.4)

The ground targets are used as references for vehicle target locations, during film analysis.

The vertically aligned targets visible in the MC rear view or MC front view provide a vertical reference line which is used to determine the MC roll angle at first MC/OV contact.

#### D.2.3.5 Dummy (see 4.3.5)

The dummy joint target locations are needed to verify that the dummy has not shifted from its standard seating position prior to MC/OV impact.

### D.2.4 Sensor specifications (see 4.4)

#### D.2.4.1 Head accelerometers (see 4.4.1.1)

The specified accelerometers are compatible with the defined accelerometer mount and with the interior space, measurement range, durability, and accuracy requirements of the specified head form. The specified accelerometer mount is compatible with the space limitations of the Hybrid III head form. The spacing and alignment of the nine accelerometers need to be standardized to ensure that the same angular accelerations and similar signal-to-noise ratios are measured for the same inputs, at all test facilities. The spacing and skewed alignment with respect to the head axes give minimum cross axis sensitivity across the full range of angular motions encountered.

#### D.2.4.2 Upper neck load cell (see 4.4.1.2)

The specified sensor is compatible with the special Hybrid III head form and upper neck mounts (see ISO 13232-3) and with the accuracy, ruggedness, range, and cross axis sensitivity requirements of the Hybrid III dummy.

#### D.2.4.3 Chest potentiometers (see 4.4.1.3)

The standard Hybrid III rotary chest displacement transducer has been replaced by a chest deflection instrumentation assembly, shown in Figure 3. This assembly consists of four string potentiometers, an upper one and a lower one, on either side of the thoracic spine box of the dummy. The use of this array is compatible with the provision of the load sensing abdomen, as the mounting brackets for the frangible abdominal insert preclude the use of the standard Hybrid III displacement transducer.

The string potentiometers are Space Age Control, Inc. 160-321V units which are specially modified for use in measuring rib deflection in frontal impact testing and have a maximum response rate of  $1,5 \text{ m/s} \pm 0,5 \text{ m/s}$  at a tension of 15,6 N. In this application this rating is further increased by the angled mounting of the potentiometer strings. As a result, a sternal velocity of up to 13,5 m/s (which is equivalent to a chest impact velocity of 50 km/h) is able to be measured.

Chest impact tests at an impact speed of approximately 3 m/s were conducted with both string pots and the original rotary pot installed in the chest of MATD. The results are shown in Figure D.1. The curves show that there is no apparent phase difference in the response of the string pots as compared to the rotary pot.

#### **D.2.4.4 Lumbar load cell (see 4.4.1.4)**

The specified sensor is compatible with the special straight lumbar spine assembly and with the accuracy, range, ruggedness, and cross axis sensitivity requirements of the Hybrid III dummy.

#### **D.2.4.5 Upper femur load cells (see 4.4.1.5)**

The specified sensor is specially designed for the motorcyclist dummy and has a much smaller outer diameter than the standard Hybrid III upper femur load cell. This is to help reduce rigid/rigid interaction with impacting structures and the resulting force magnification that may occur. Such magnification due to direct sensor impact may still occur, but it is less severe than with the standard load cell. Otherwise, the specified load cell is compatible with the geometry, accuracy, range, ruggedness, and cross axis sensitivity requirements of the frangible femur bones and Hybrid III leg components.

#### **D.2.4.6 Frangible leg bone strain gauges (see 4.4.1.6)**

The locations for the femur and tibia strain gauges are specified in order that comparable measurements will be made by different test facilities. The specific gauge and installation details are also specified because these will influence the accuracy, drift, and comparability of measurements made at different test facilities. The specifications lie within what is considered common strain gauge practice.

#### **D.2.4.7 Mechanical (see 4.4.2)**

These four sensors are needed in order to measure the injury variables for these four body regions.

### **D.2.5 Internal data acquisition and recording system specifications (see 4.5)**

An internal data acquisition system is recommended in order to prevent distortion of dummy motions which can be caused by external electrical cables. Past test experience indicates that such cables can influence test results by: applying forces (due to cable inertia, or to catching on other objects) to the dummy which may vary in amplitude and direction; impacting the dummy itself, during various phases of the crash test; wrapping around various dummy appendages; increasing the likelihood of data dropouts due to connector disruption; or obstructing photographic camera views and film data acquisition. Long cables (e.g., 30 m) typically require special impedance matching. Internal data acquisition systems are feasible and available for this type of application and a 32-channel unit has been used in motorcycle crash tests.

#### **D.2.5.1 Not recommended external cables (see 4.5.1)**

The use of external cables is not recommended because they can distort dummy kinematics due to cable inertial effects, impacts with the dummy, or tension effects. Currently, there is no method available to guarantee such effects will not occur. The tension effect is illustrated by ATB computer simulations of configuration 143 with a 13,4 m/s OV impacting a stationary motorcycle. The model used an ATB harness model to connect the rear of the dummy's pelvis to the right rear portion of the motorcycle seat to determine the effects of one or more cables catching on some part of the motorcycle. The stiffness and strength of these cables were determined from laboratory measurements of a cable that meets the requirements of 4.5.1 (Figure D.2). However, it should be noted

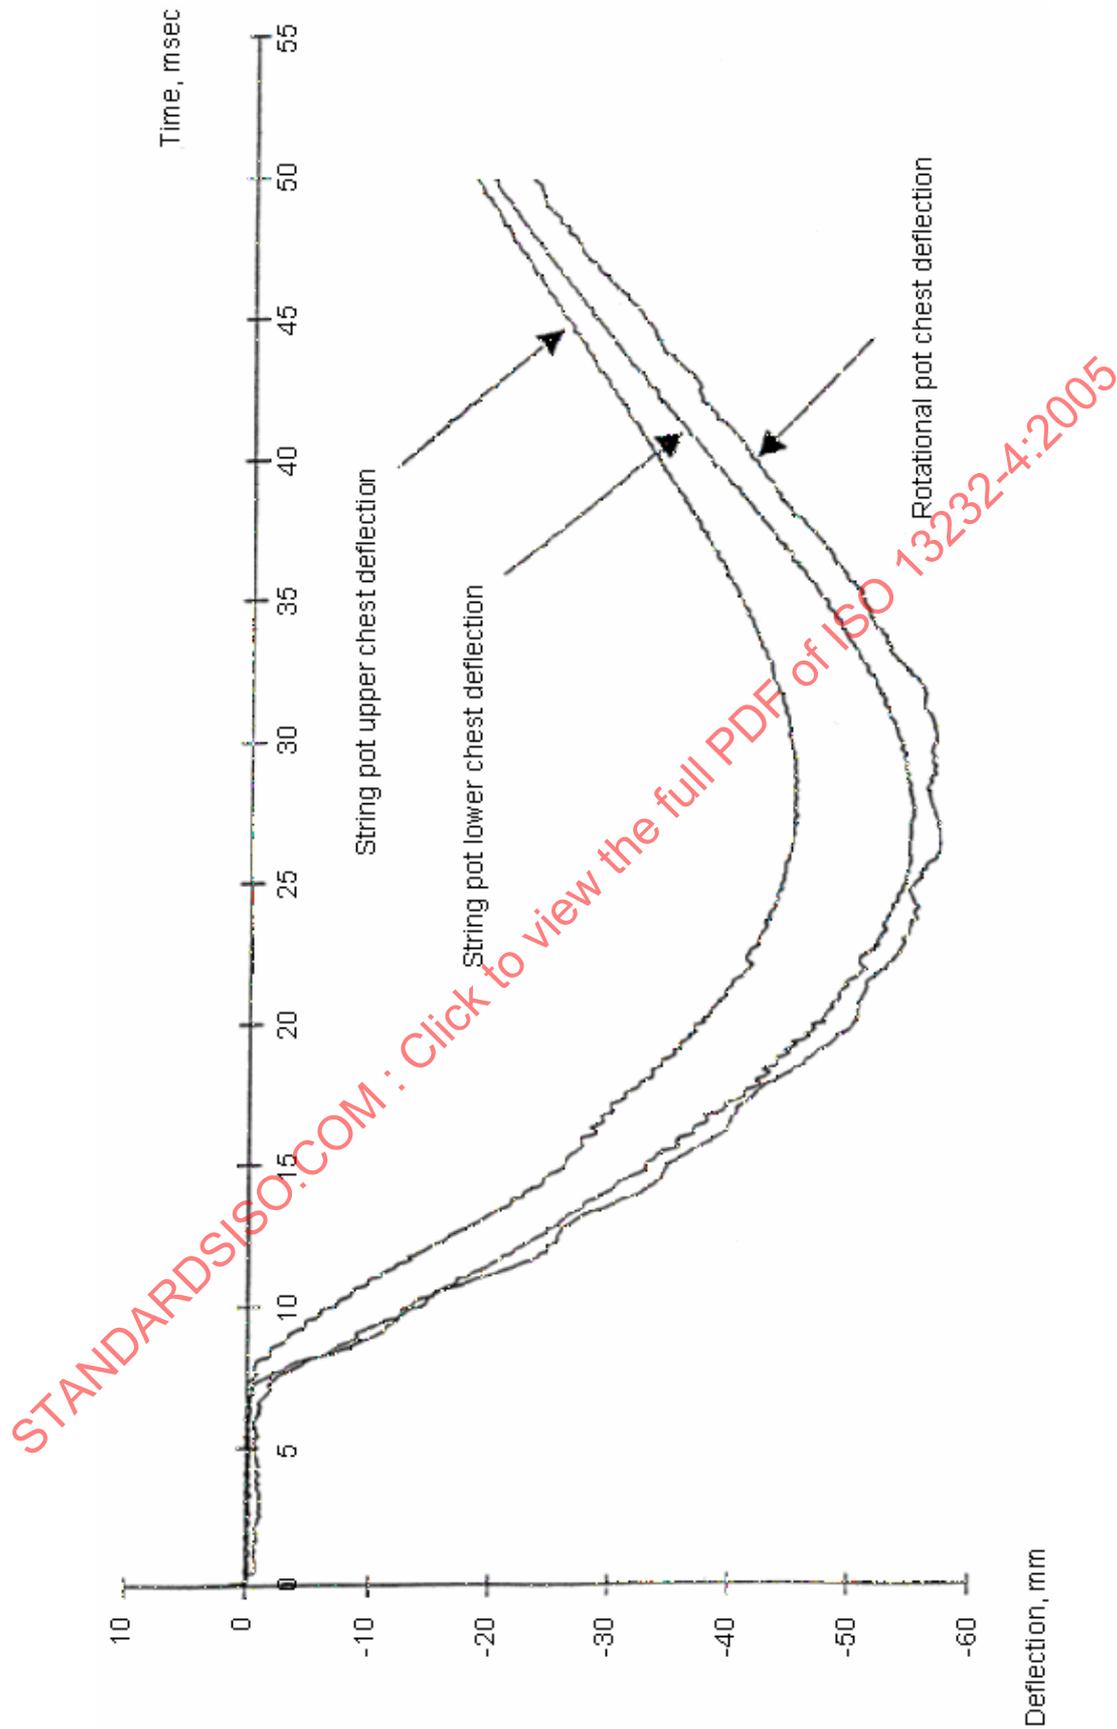

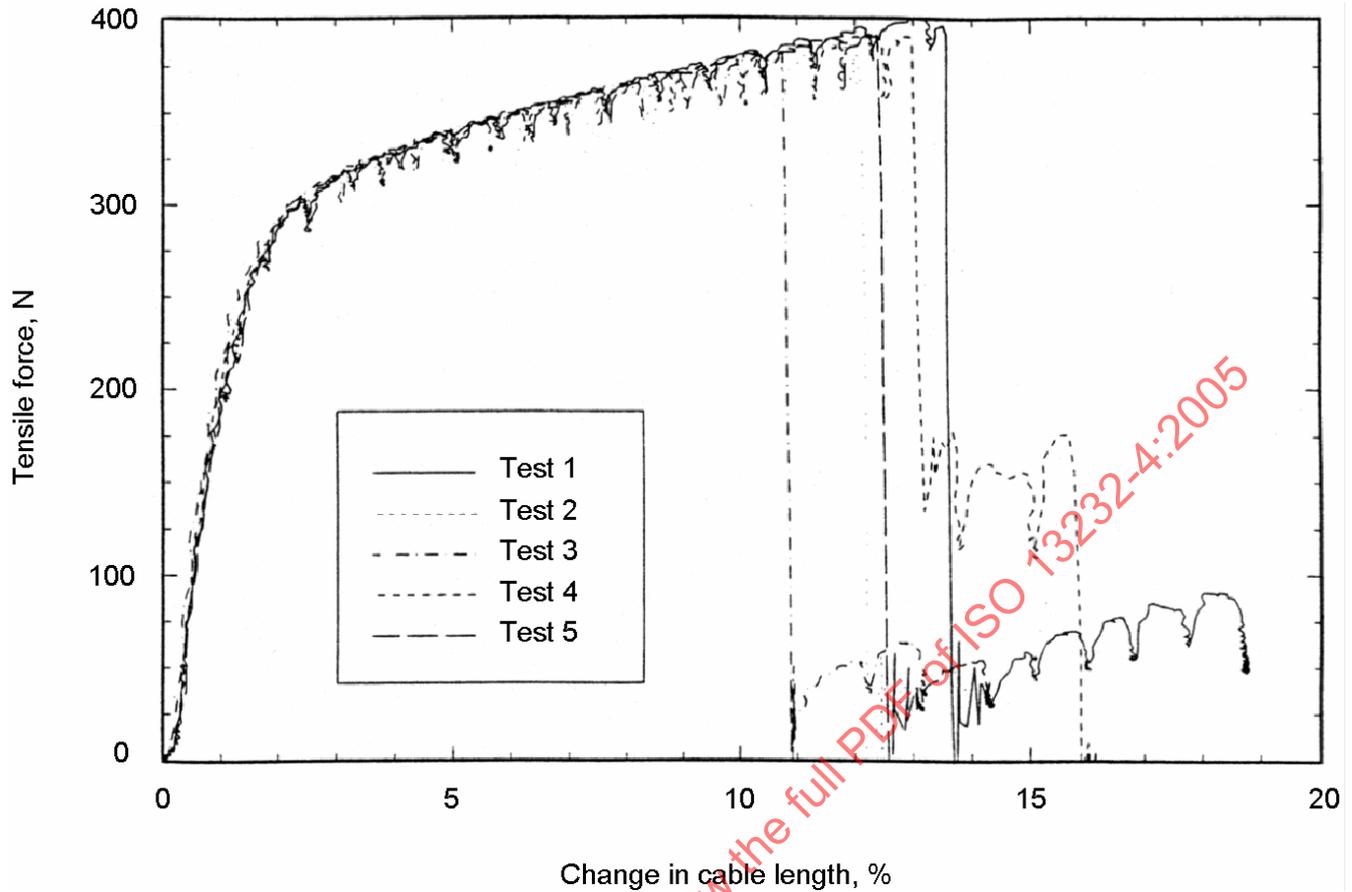

Figure D.1 — Rotational chest pot and string pot time history responses to impact when mounted in the Hybrid III chest

**Figure D.2 — Force/deflection properties of example cables**

that maximum cable strength is not specified in 4.5.1, and the strength could be much greater (and the motion distortion much worse) than that used here (approximately 400 N).

Figures D.3 through D.7 show the effects of one cable catching and breaking. Only slight distortion of the motion occurs with this particular cable breaking strength. Figures D.8 through D.12 show the effects of 12 cables catching and deforming. In this case, the cables are stretched and undergo plastic deformation, but do not break. The dummy motion is greatly affected. Catching of more than one cable or use of stronger cables would also be expected to distort the motion. Such distortions due to cable effects are not biofidelic, and can lead to variations between tests, and among test facilities.

Temporary self-detaching cables to supply initial power and the signal from the initial MC/OV contact sensor are permissible providing that they detach at a maximum force of 5 N. From experience with the feasible design, this detachment occurs in the initial impact period and is of insufficient magnitude to significantly affect dummy motion.

The rear portion of the pelvis is the customary attachment location for the Hybrid III dummy. Also it is near the centre of gravity of the total dummy, and therefore, should help to minimize the distortion of limb or torso motion. Use of an attached connector for strain relief is considered to be good standard practice.

The use of nondetachable external cables according to the technical specification which is provided in 4.5.1, though not recommended, in some cases may not significantly affect dummy motion. This was demonstrated at the Transport Research Laboratory (TRL) by the results of practical experiment. A series of five tests using an U.K. Standard Occupant Protection Assessment Test Dummy (OPAT) dummy in free flight, i.e., no external cables, was undertaken on an indoor impact rig. The dummy was mounted on a Norton motorcycle adapted so that it could be fitted to the impact rig sled; this was then accelerated to a velocity of 13.4 m/s before being brought to rest by an acceleration pulse of approximately  $-20 \text{ m/s}^2$ . The pulse was determined by experiment whereby the acceleration time history of the sled, which is controlled by the deformation of crumple tubes, was matched approximately to that of an equivalent full-scale test of an impact of a Norton motorcycle and OPAT dummy at a relative heading angle of
